1. Introduction

1.1. Time-to-event data

Consider a non-negative random variable $T \geq 0$, which can be interpreted as the moment when a certain event occurs, or a waiting time for the event. There are numerous examples of such random variables in applications of different nature:

- The event is the death of a person; T is the time of death or the survival time.
- The event is an occurrence of a disease in a previously healthy person; T is the time of diagnosis.
- The event is the failure of a machine or device; T is time to failure.
- The event is the repair of a broken machine; T is duration of maintenance.
- The event is the default of a debtor; T is time to default.
- The event is an occurrence of an insurance claim; T is the time when the claim is made.
- The event terminates the payment of a pension (e.g. the death of the pensioner); T is the total amount paid on the pension. (In this example, *time is money*.)

The theory of time-to-event analysis bears various names depending on the field of application: it is called *survival analysis*^{*} in biomedical applications, *life tables*[†] in demographics and life insurance, *reliability theory*[‡] in technical applications, *credit risk*[§] and *insurance risk*[¶] in financial applications and non-life insurance.

1.2. Censoring

Standard statistical methods for estimation and testing could be used for the analysis of time-to-event data if event times could be observed on all participating subjects. However, this is usually not the case. Events such as default on a debt or diagnosis of a specific disease may not occur at all for some subjects. Even if the event does eventually occur, it may take a long time to develop and so would not be observed. Thus, time-to-event data are usually incompletely observed and therefore require specialized analysis methods.

The fact that events may not be observed can be built into the probabilistic model by introducing two latent random variables: $T \geq 0$ and $C \geq 0$. The variable T is the time to event^{||} (*failure time*, *survival time*), the variable C is called *censoring time*^{**} and expresses

^{*} Český *analýza přežití* [†] Český *úmrtnostní tabulky* [‡] Český *teorie spolehlivosti* [§] Český *kreditní riziko*

[¶] Český *pojistné riziko* ^{||} Český *dobu do události* ^{**} Český *čas censorování*

the duration of observation of the subject. If the duration of observation is shorter than the failure time, the failure time is not observed. Thus, the pair (T, C) generates the following two case:

- If $T \leq C$, T is observed and C is not observed.
- If $C < T$, C is observed and T is not observed.

The possibility that the event may not occur at all can be expressed by a very large T or even $T = \infty$. Let $X = \min(T, C)$ be *the censored failure time*^{*} and let $\delta = \mathbb{1}(T \leq C)$ be *the failure indicator*[†].

Notation. Let A be a random event, define $\mathbb{1}(A) = 1$ if A occurs and $\mathbb{1}(A) = 0$ if A does not occur. The random variable $\mathbb{1}(A)$ is called *the indicator of A* .

Notation. Let s, t be real numbers. Denote $s \wedge t = \min(s, t)$.

Consider latent failure and censoring times $(T_1, C_1), \dots, (T_n, C_n)$ generated for n independent subjects. If we could observe T_1, \dots, T_n , we could perform standard statistical procedures on this random sample. However, we only observe censored failure times and failure indicators $(X_1, \delta_1), \dots, (X_n, \delta_n)$. Such censored data requires specialized methods of statistical analysis.

In general, the censoring variables C_1, \dots, C_n are considered random variables with certain distributions (in principle, each C_i may have a different distribution function). This is called the *random censorship model*. There are two special case of this general model that acquired their own names:

Type I censoring All censoring variables are equal to a pre-specified constant τ that expresses the common maximal duration of observation, i.e., $C_i = \tau$ for all i almost surely[‡].

Type II censoring All remaining observations are censored when the k -th failure occurs (where $k \in \{1, \dots, n\}$ is pre-specified), i.e., $C_i = T_{(k)}$ for all i , $T_{(k)}$ is the k -th order statistic of the random sample T_1, \dots, T_n [§].

These two censoring schemes are used primarily in technical applications. They are unrealistic for most biomedical and financial applications.

1.3. Survival function, hazard function

The distribution of a non-negative random variable T is usually described by its distribution function $F(t) = P[T \leq t]$ or a density $f(t)$ with respect to a σ -finite measure μ , a function such that $F(t) = \int_0^t f(s) d\mu(s)$.

* Český *sensorovaná doba do události* † Český *indikátor události* ‡ Český *sensorování typu I, sensorování časem* § Český *sensorování typu II, sensorování poruchou*

When working with censored failure time data, it is of advantage to work with survival functions instead of distribution functions.

Definition 1.1. The function $S(t) = 1 - F(t) = P[T > t]$ is called the *survival function* of a random variable T with distribution function $F(t)$. ∇

Notation. Let f be a right-continuous function. Define $f(t-) = \lim_{h \searrow 0} f(t-h)$ (if the limit exists). This is a left-continuous function.

Note. Let $S(t)$ be the survival function of a non-negative random variable T with distribution function $F(t)$.

- $S(t)$ is non-increasing right-continuous function, $S(0) = 1$, $\lim_{t \rightarrow \infty} S(t) = 0$.
- If T is continuous with density $f(t)$ w.r.t. the Lebesgue measure then $f(t) = -S'(t)$ and $S(t) = \int_t^\infty f(s) ds$.
- If T is discrete with values t_1, t_2, \dots and $p_i = P[T = t_i]$ then $p_i = S(t-) - S(t)$ and $S(t) = \sum_{\{i:t_i > t\}} p_i$.

The expectation of a non-negative random variable is defined as $E T = \int_0^\infty t dF(t)$. The following lemma shows that the expectation can be obtained by integrating the survival function.

Lemma 1.1. Let $T \geq 0$ a.s. and $E T < \infty$. Then

$$E T = \int_0^\infty S(t) dt. \quad \diamond$$

This result can be easily generalized to random variables that can attain negative values and to higher moments.

*The end of
lecture 1
(Oct. 3)*

Corollary. Let X be a random variable such that $E |X|^\alpha < \infty$. Then

$$E |X|^\alpha = \alpha \int_0^\infty t^{\alpha-1} P[|X| > t] dt.$$

Lemma 1.1 can be useful for estimation of the expectation from censored data. It is unclear how to generalize the arithmetic mean to censored data. However, if an estimator $\widehat{S}(t)$ of survival function can be found on the whole interval $\langle 0, \infty \rangle$, the expectation could be estimated by $\int_0^\infty \widehat{S}(t) dt$.

It is known that the distribution of a random variable can be described by density, distribution function, survival function, quantile function or characteristic function. However, there is another way to describe the distribution, called *the hazard function**; it is especially useful for time-to-event data.

* Český *risiková funkce*

Definition 1.2. Let T be a continuous non-negative random variable. Then the *hazard function* $\lambda(t)$ of T is defined as

$$\lambda(t) = \lim_{h \searrow 0} \frac{1}{h} \mathbb{P}[t \leq T < t + h | T \geq t].$$

Let T be discrete with values $0 \leq t_1 < t_2 < \dots$. Then the *hazard function* $\lambda(t)$ of T is defined at t_1, t_2, \dots by

$$\lambda(t_i) \equiv \lambda_i = \mathbb{P}[T = t_i | T \geq t_i]. \quad \nabla$$

Loosely speaking, the hazard function measures the probability of having the event at the time t (or shortly thereafter) given that the event had not occurred earlier. Thus, it expresses the risk of having the event at t . The hazard function may have different names in different application areas: in reliability theory, where the event of interest is a failure of a machine, it is called *failure rate*^{*} (or failure intensity); in epidemiology, where the event of interest is occurrence of disease, it is called *incidence rate*[†] (or incidence function); in demography or insurance, where the event of interest is death, it is called *mortality rate*[‡].

Notation. The function $\Lambda(t)$ defined as

$$\Lambda(t) = \int_0^t \lambda(s) ds$$

for continuous t , and

$$\Lambda(t) = \sum_{\{i: t_i \leq t\}} \lambda(t_i)$$

for discrete T , is called the *cumulative hazard function*[§].

The next result shows that the hazard function really characterizes the whole distribution and reveals its relationship to the density and the survival function.

Theorem 1.2. Let T be a non-negative random variable with hazard function λ , density f , distribution function F and survival function $S = 1 - F$. Then

(i)

$$\lambda(t) = \frac{f(t)}{S(t-)}.$$

(ii)

$$\Lambda(t) = \int_0^t \frac{dF(s)}{S(s-)}. \quad (1.1)$$

* Český intenzita poruch † Český incidence choroby ‡ Český úmrtnost § Český kumulativní riziko

1. Introduction

(iii)

$$S(t) = e^{-\Lambda(t)}, \quad (1.2)$$

for discrete T with values $0 \leq t_1 < t_2 < \dots$,

$$S(t) = \prod_{\{i: t_i \leq t\}} (1 - \lambda_i). \quad (1.3)$$

◇

Corollary. For continuous T ,

$$f(t) = \lambda(t)e^{-\Lambda(t)},$$

for discrete T with values $0 \leq t_1 < t_2 < \dots$,

$$P[T = t_i] = \lambda_i \prod_{\{j: t_j < t_i\}} (1 - \lambda_j).$$

There is yet another way to characterize a failure time distribution, which is useful especially in engineering, demographics and life insurance: mean residual lifetime.

Definition 1.3. Let $T \geq 0$ a.s. The function $r(t) = E[T - t | T \geq t]$ is called *the mean residual lifetime**. ▽

Clearly, $r(0) = E T$.

Theorem 1.3. Let T be a non-negative random variable with survival function S and mean residual lifetime r . Then

- (i) The conditional survival function of T given $T \geq t$ is $P[T > s | T \geq t] = S(s)/S(t-)$ for $s \geq t$.
- (ii) The mean residual lifetime of T can be expressed as

$$r(t) = \frac{\int_t^\infty S(s) ds}{S(t-)}.$$

(iii) For continuous T and any $t \geq 0$,

$$S(t) = \frac{E T}{r(t)} \exp\left\{-\int_0^t \frac{ds}{r(s)}\right\}. \quad \diamond$$

The last point of this theorem proves that the mean residual lifetime as a function defined on $(0, \infty)$ specifies completely the failure time distribution.

1.4. Independent censoring

Suppose the failure time T is censored – instead of T , we observe the pair (X, δ) , where $X = \min(T, C) = T \wedge C$, $\delta = \mathbb{1}(T \leq C)$ and C is the censoring variable. We are interested in the distribution of T : the survival function $S(t) = P[T > t]$ or the hazard function $\lambda(t) = f(t)/S(t-)$. It is clear that the task requires imposing certain conditions on the censoring variable C .

Suppose that the random variables T and C are stochastically independent. The failure time T is not directly observed. First, consider the survival function of X :

$$S_X(t) = P[X > t] = P[T > t, C > t] = S(t)P[C > t] \leq S(t).$$

Clearly, it is difficult to recover the survival function of T in this way even if C is independent, unless we know the distribution of C . Next, consider the survival function of X given that X is uncensored:

$$S_X^*(t) = P[T > t | T \leq C] = \frac{P[t < T \leq C]}{P[T \leq C]} \neq S(t).$$

This expression is even less useful for recovering the survival function of T .

Finally, consider the hazard function $\lambda(t)$ of a continuous failure time variable T

$$\begin{aligned} \lambda(t) &= \lim_{h \searrow 0} \frac{1}{h} P[t \leq T < t + h | T \geq t] \stackrel{(*)}{=} \lim_{h \searrow 0} \frac{1}{h} P[t \leq T < t + h | T \geq t, C \geq t] \\ &= \lim_{h \searrow 0} \frac{1}{h} P[t \leq T < t + h | X \geq t], \end{aligned} \tag{1.4}$$

where the equation (*) holds because of independence. Thus, the hazard function of T can be recovered from censored data under certain conditions if we look at the occurrence of death among subjects who are alive and still uncensored at the particular time of interest. This is the reason why the hazard function is so convenient tool for the analysis of censored data.

Stochastic independence between T and C is a sufficient but not a necessary condition for equation (1.4). Therefore we take that equation and make it a definition of “independent censoring”.

Definition 1.4. Let T be continuous and let $\lambda(t) = \lim_{h \searrow 0} \frac{1}{h} P[t \leq T < t + h | T \geq t]$ be its true hazard function (called *the net hazard* in this context). Let $\lambda^\#(t) = \lim_{h \searrow 0} \frac{1}{h} P[t \leq T < t + h | X \geq t]$ be the hazard function of T in the presence of censoring (called *the crude hazard*). The censoring variable C satisfies *the independent censoring condition** if and only if $\lambda(t) = \lambda^\#(t)$ a.e., that is, when the net and crude hazards are equal. ∇

Generalization of the independent censoring condition to arbitrary failure time distributions will be considered in Chapter 3.

* Český nezávislé censorování

1. Introduction

We will always assume that independent censoring condition holds. Below is a rather trivial example where T and C are clearly not independent but the independent censoring condition is still satisfied.

Example (Type II censoring). Consider independent latent failure times T_1, \dots, T_n and define $C_i = T_{(k)}$ for all i , $1 \leq k \leq n$. Then C_i is not independent of T_i but the independent censoring condition (1.4) holds for each i . \triangle

2. Parametric Models

2.1. Parametric likelihood for arbitrary random censoring

Let $(T_1, C_1), \dots, (T_n, C_n)$ be independent, let $X_i = \min(T_i, C_i) = T_i \wedge C_i$ be the censored failure times and $\delta_i = \mathbb{1}(T_i \leq C_i)$ the failure indicators. The data consist of independent pairs $(X_1, \delta_1), \dots, (X_n, \delta_n)$.

Let T_1, \dots, T_n be identically distributed with survival function $S(x; \theta)$, density $f(x; \theta)$, and hazard function $\lambda(x; \theta)$, where $\theta \in \Theta$ is a p -dimensional parameter vector. Suppose the family of densities $f(x; \theta)$ satisfies the regularity assumptions of the maximum likelihood theory.

Denote by $G_i(x)$ the survival function of the censoring variable C_i and by $g_i(x)$ its density. We are not assuming that the censoring times are equally distributed; arbitrary distributions are allowed for each of them. However, we will assume throughout this section that T_i and C_i are stochastically independent.

The likelihood function is based on the product (over i) of joint densities of the observations (X_i, δ_i) .

Lemma 2.1. *The joint density of (X_i, δ_i) is*

$$q_i(x, \delta) = [f(x; \theta)G_i(x-)]^\delta [g_i(x)S(x; \theta)]^{1-\delta}. \quad \diamond$$

The proof of Lemma 2.1 is relatively easy when the distribution of X_i is continuous (that proof was shown at the lecture). However, continuity of X_i requires all C_i 's to have continuous distributions. In real applications, censoring times often follow mixtures of discrete and continuous distributions. Therefore we present here a proof of the most general case, when both T_i and C_i have discrete and continuous components.

Proof. Let $S_1 = \{x \in \mathbb{R} : P[T_i = x] > 0\}$ and $S_2 = \{x \in \mathbb{R} : P[C_i = x] > 0 \text{ for some } i\}$ be countable sets that include the possible discrete values of failure times and censoring times, respectively. Suppose the sets have at most finitely many points within any bounded subset of \mathbb{R} . Suppose the distributions of T_i and C_i are all absolutely continuous with respect to the measure $\lambda + \mu_{S_1 \cup S_2}$, where λ is the Lebesgue measure and $\mu_{S_1 \cup S_2}$ is the counting measure on the set $S_1 \cup S_2$. Then there exists a density $f(t)$ of T_i such that

2. Parametric Models

$S(t) = \int_{(t, \infty)} f(s) d\mu(s)$, which can be written down as $f(t) = f^*(t) + \Delta S(t)$, where

$$f^*(t) = \lim_{h \searrow 0} \frac{S(t) - S(t+h)}{h}$$

and $\Delta S(t) = S(t-) - S(t) = P[T_i = t]$.

Similarly, there exist densities $g_i(t)$ of C_i such that $G_i(t) = \int_{(t, \infty)} g_i(s) d\mu(s)$, which can be written down as $g_i(t) = g_i^*(t) + \Delta G_i(t)$, where

$$g_i^*(t) = \lim_{h \searrow 0} \frac{G_i(t) - G_i(t+h)}{h}$$

and $\Delta G_i(t) = G_i(t-) - G_i(t) = P[C_i = t]$.

Because T_i and C_i are independent, they have a joint density $h_i(t, s)$ with respect to the product measure $\mu \otimes \mu$ and $h_i(t, s) = f(t)g_i(s)$.

Since $X_i = T_i \wedge C_i$, the observation (X_i, δ_i) has a joint density $q_i(x, \delta)$ with respect to the product measure $\mu \otimes \mu_{\{0,1\}}$. First, evaluate it at $\delta = 1$. It is a sum of a continuous and a discrete component that can be obtained as

$$\lim_{h \searrow 0} \frac{P[X_i > x, \delta_i = 1] - P[X_i > x+h, \delta_i = 1]}{h} + P[X_i = x, \delta_i = 1]$$

The continuous component can be also written as $-\frac{d^+}{dx} P[X_i > x, \delta_i = 1]$, where the derivative is taken from the right. Calculate

$$\begin{aligned} P[X_i > x, \delta_i = 1] &= P[x < T_i \leq C_i] = \int_{(x, \infty)} \left[\int_{(t, \infty)} h_i(t, s) d\mu(s) \right] d\mu(t) \\ &= \int_{(x, \infty)} f(t) \int_{(t, \infty)} g_i(s) d\mu(s) d\mu(t) = \int_{(x, \infty)} f(t) G_i(t-) d\mu(t). \end{aligned}$$

The right derivative of this expression with respect to x is $f^*(x)G_i(x-)$, because $\Delta S(t) = 0$ on $\langle x, x+h \rangle$ for h sufficiently small.

Next, calculate

$$P[X_i = x, \delta_i = 1] = P[T_i = x, C_i \geq x] = P[T_i = x] P[C_i \geq x] = \Delta S(x) G_i(x-).$$

Summing the two results, we get

$$q_i(x, 1) = [f^*(x) + \Delta S(x)] G_i(x-) = f(x) G_i(x-).$$

For $\delta = 0$, we show by the same technique that

$$P[X_i > x, \delta_i = 0] = P[x < C_i < T_i] = \int_{(x, \infty)} g_i(t) S(t) d\mu(t)$$

and $P[X_i = x, \delta_i = 0] = \Delta G_i(x) S(x)$. This leads to the desired result. □

Theorem 2.2. *The likelihood function for θ has the form*

$$L(\theta) = C \prod_{i=1}^n \left[\lambda(X_i; \theta) \frac{S(X_i; \theta)}{S(X_i; \theta)} \right]^{\delta_i} S(X_i; \theta).$$

When the distribution of T_i is continuous,

$$L(\theta) = C \prod_{i=1}^n [\lambda(X_i; \theta)]^{\delta_i} S(X_i; \theta),$$

and the log-likelihood can be written as

$$\ell(\theta) = \sum_{i=1}^n \left[\delta_i \log \lambda(X_i; \theta) - \int_0^{X_i} \lambda(t; \theta) dt \right] + c. \quad \diamond$$

Thus, the likelihood does not depend on the censoring distributions — as long as the censoring distributions do not involve the parameter θ . This requirement is called *uninformative censoring*.

Now, standard results of the maximum likelihood theory can be applied to obtain the maximum likelihood estimator of θ and its asymptotic distribution. For most failure time distributions, however, the score function and the information matrix are not easy to calculate. In the next two sections, we consider two special cases involving the exponential failure time distribution, which is the easiest to handle.

*The end of
lecture 3 (Oct.
12)*

2.2. Exponential distribution with Type II censoring

Let T_1, \dots, T_n be identically distributed with exponential distribution $\text{Exp}(\lambda)$. The density and survival function of T_i is

$$f(t; \lambda) = \lambda e^{-\lambda t} \quad \text{and} \quad S(t; \lambda) = e^{-\lambda t},$$

respectively. The hazard function is $\lambda(t) = \lambda$. Consider Type II censoring, that is, take a fixed $k \in \{1, \dots, n\}$ and set $C_i = T_{(k)}$ for all i , where $T_{(k)}$ is the k -th order statistic of the random sample T_1, \dots, T_n .

The arguments made in the previous section do not apply to this case because T_i and C_i are not independent. The observed data $(X_1, \delta_1), \dots, (X_n, \delta_n)$ are contained in the values of the first k order statistics, so the likelihood will be based on the joint distribution of $(T_{(1)}, \dots, T_{(k)})$.

Lemma 2.3. *The joint density of $(T_{(1)}, \dots, T_{(k)})$ is*

$$h(t_1, \dots, t_k) = \frac{n!}{(n-k)!} \lambda^k e^{-\lambda \sum_{i=1}^k t_i + (n-k)t_k} \quad \text{when } 0 < t_1 < t_2 < \dots < t_k,$$

and $h(t_1, \dots, t_k) = 0$ otherwise. \(\diamond\)

This result allows us to form the likelihood.

Theorem 2.4. *The likelihood function for exponential data with Type II censoring is*

$$L(\lambda \mid T_{(1)}, \dots, T_{(k)}) = \frac{n!}{(n-k)!} \lambda^k e^{-\lambda S_{k,n}},$$

where

$$S_{k,n} = \sum_{i=1}^k T_{(i)} + (n-k)T_{(k)}$$

is the sufficient statistic. ◇

It turns out that the likelihood has the same form as that derived in Theorem 2.2, except the irrelevant multiplicative factor. Maximizing the likelihood, we get the likelihood equation $k/\hat{\lambda} - S_{k,n} = 0$, leading to the MLE $\hat{\lambda} = k/S_{k,n}$ and to the MLE of the expected failure time

$$\hat{\mu} = \frac{1}{\hat{\lambda}} = \frac{1}{k} \sum_{i=1}^k T_{(i)} + \frac{n-k}{n} T_{(k)}.$$

Using the transformation $U_i = (n-i+1)(T_{(i)} - T_{(i-1)})$ for $i = 1, \dots, k$ with $T_{(0)} \equiv 0$, we can show that $\sum_{i=1}^k U_i = S_{k,n}$ and that U_1, \dots, U_k are iid with distribution $\text{Exp}(\lambda)$. This argument is used to derive the exact distribution of the sufficient statistic shown in the following theorem.

Theorem 2.5. *Let T_1, \dots, T_n be independent and identically distributed with distribution $\text{Exp}(\lambda)$, let $S_{k,n} = \sum_{i=1}^k T_{(i)} + (n-k)T_{(k)}$. Then*

$$2\lambda S_{k,n} \sim \chi_{2k}^2. \quad \diamond$$

This theorem provides the basis for conducting exact parametric inference for exponential distribution with Type II censoring. Consider testing

$$H_0 : \lambda = \lambda_0 \quad \text{and} \quad H_1 : \lambda \neq \lambda_0.$$

The test that rejects H_0 when

$$2\lambda_0 S_{k,n} < \chi_{2k}^2(\alpha/2) \quad \text{or} \quad 2\lambda_0 S_{k,n} > \chi_{2k}^2(1 - \alpha/2),$$

where $\chi_f^2(\alpha)$ is the α -quantile of the χ_f^2 distribution, has level exactly α and it is the most powerful test of H_0 in the current model. Similarly, an exact confidence interval for λ with coverage $1 - \alpha$ is

$$\left(\frac{\chi_{2k}^2(\alpha/2)}{2S_{k,n}}, \frac{\chi_{2k}^2(1 - \alpha/2)}{2S_{k,n}} \right).$$

This is the only case when exact inference is possible with censored data.

*The end of
lecture 4
(Oct. 17)*

2.3. Exponential regression with arbitrary random censoring

In this section, we use the results of Section 2.1 to investigate a regression model for censored exponentially distributed response. Let T_1, \dots, T_n be distributed according to $\text{Exp}(\lambda_i)$ and let C_1, \dots, C_n be independent of each other and independent of T_1, \dots, T_n , with arbitrary distributions. We observe independent triplets

$$(X_1, \delta_1, \mathbf{Z}_1), \dots, (X_n, \delta_n, \mathbf{Z}_n),$$

where $X_i = T_i \wedge C_i$, $\delta_i = \mathbb{1}(T_i \leq C_i)$, and \mathbf{Z}_i are random covariate vectors of dimension p , typically with the first component equal to one.

Suppose there exists a p -vector $\boldsymbol{\beta}$ of regression parameters such that

$$\lambda_i = e^{\boldsymbol{\beta}^\top \mathbf{Z}_i}.$$

According to Theorem 2.2, the likelihood function for $\boldsymbol{\beta}$ has the form

$$L(\boldsymbol{\beta}) = C \prod_{i=1}^n \lambda_i^{\delta_i} e^{-\lambda_i X_i},$$

the log-likelihood is

$$\ell(\boldsymbol{\beta}) = \sum_{i=1}^n (\delta_i \boldsymbol{\beta}^\top \mathbf{Z}_i - e^{\boldsymbol{\beta}^\top \mathbf{Z}_i} X_i) + c,$$

and the score statistic is

$$\mathbf{U}(\boldsymbol{\beta}) = \sum_{i=1}^n (\delta_i - e^{\log X_i + \boldsymbol{\beta}^\top \mathbf{Z}_i}) \mathbf{Z}_i.$$

This is equivalent to the score statistic of a Poisson loglinear model with δ_i as the response and $\log X_i$ as the offset (see the notes for Advanced Regression Models). Algorithms for finding the maximum likelihood estimator of $\boldsymbol{\beta}$, calculating the observed information matrix, approximating the distribution of the estimated $\boldsymbol{\beta}$, performing tests about $\boldsymbol{\beta}$ and building confidence intervals are all taken from the Poisson loglinear model. Any software that can fit loglinear models can be used to perform exponential regression with arbitrary independent censoring.

3. Counting Processes and Martingales

From now on, we turn our attention to nonparametric methods for censored data. To this end, we change the standard formulation of a censored observation (X, δ) , where $X = T \wedge C$ and $\delta = \mathbb{1}(T \leq C)$, into a pair of stochastic processes.

One can view the problem of awaiting a failure of a subject as a process evolving in time. At time $t = 0$, we start following the subject and wait for the failure. Once we observe one, we mark the subject as having failed at that moment. If the subject is censored before a failure occurs, the follow-up is terminated and the subject is no longer at risk for failure.

This consideration motivates the following formulation of the problem. Let $N(t)$ be a stochastic process defined as

$$N(t) = \mathbb{1}(T \leq t, \delta = 1)$$

and define another process $Y(t)$ as

$$Y(t) = \mathbb{1}(X \geq t).$$

The *counting process*^{*} $N(t)$ counts the number of failures that were observed prior to or at the time t . In our case, $N(t)$ starts at 0 at the time $t = 0$, jumps to 1 at the failure time, and stays at 1 thereafter. The *at-risk process*[†] $Y(t)$ indicates whether or not the subject is under observation at the time t . It starts at 1 at $t = 0$ and drops to 0 as soon as the failure occurs or the subject is censored.

Obviously, $Y(t) = 0$ implies that a potential failure at time t cannot be observed. Thus, due to censoring, we cannot fully observe the “uncensored” counting process $\mathbb{1}(T \leq t)$.

The counting process notation is useful in several ways. First, by emphasizing the underlying time component of the censored data problem, it leads to the utilization of the martingale theory based on conditioning upon the past. This simplifies the problem in many important ways. Second, it can be easily generalized to allow for late entry into the observation period (i.e., at time $t_0 > 0$), repeated change in the at-risk status, and direct modeling of various time-varying features (such as covariates that change over time).

Before we start exploring the properties of censored data via counting processes, we generalize the independent censoring condition first formulated for continuous data in Definition 1.4 to arbitrary failure time distributions.

* Český čítací proces † Český pozorovací proces

Definition 3.1. The censoring variable C satisfies *the independent censoring condition* for the failure time T with cumulative hazard Λ if and only if

$$\Lambda(t) = - \int_0^t \frac{dP [T \geq s, C \geq T]}{P [T \geq s, C \geq s]} \quad \forall s \text{ such that } P [T \geq s, C \geq s] > 0. \quad (3.1)$$

▽

Note. When the distribution of T is continuous, condition (3.1) is equivalent to equality

$$\begin{aligned} \lambda(t) &= \frac{-\frac{\partial}{\partial s} P [T \geq s, C \geq t] \Big|_{s=t}}{P [T \geq t, C \geq t]} \\ &= \lim_{h \searrow 0} \frac{1}{h} P [t \leq T < t + h | T \geq t, C \geq t] \quad \forall t \geq 0. \end{aligned}$$

The net hazard on the left should be equal to the crude hazard on the right, as required by Definition 1.4. Definition 3.1 is written in a less intuitive way but applies to distributions with discrete components as well.

We will always assume that the independent censoring condition holds.

3.1. Doob-Meyer decomposition

Our most important tool will be the Doob-Meyer decomposition of a submartingale.

Theorem 3.1 (Doob-Meyer). *Let $X(t)$ be a right-continuous non-negative \mathcal{F}_t -submartingale. Then there exists a unique (up to sets of measure zero) right-continuous martingale $M(t)$ and a non-decreasing right-continuous \mathcal{F}_t -predictable process $A(t)$ such that $A(0) = 0$, $E A(t) < \infty$, and*

$$X(t) = M(t) + A(t) \quad \text{almost surely}$$

for any $t \geq 0$. In addition, if $X(t)$ is bounded then $M(t)$ is uniformly integrable and $A(t)$ is integrable. ◇

Note.

- The process $A(t)$ is called the *compensator*^{*} for the submartingale $X(t)$. In general, it depends on the filtration \mathcal{F}_t .
- Suppose $X(0) = 0$. Then $M(0) = 0$, $E M(t) = 0$, and the martingale $M(t)$ represents the “random noise” part of $X(t)$ while the compensator $A(t)$ can be regarded as the “systematic” part of X .
- Left-continuous adapted processes are always predictable. The compensator $A(t)$ from the Doob-Meyer theorem is right-continuous and still predictable.

^{*} Český kompenzátor

Recall that a single censored observation can be described as the pair of stochastic processes $N(t) = \mathbb{1}(T \leq t, \delta = 1)$ and $Y(t) = \mathbb{1}(X \geq t)$ or, equivalently, as the pair of counting processes $N(t) = \mathbb{1}(T \leq t, \delta = 1)$ and $N^U(t) = \mathbb{1}(C \leq t, \delta = 0)$. Introduce the natural filtration summarizing the history of observed failure and censoring times up to time t :

$$\mathcal{F}_t = \sigma\{N(s), Y(s), 0 \leq s \leq t\} = \sigma\{N(s), N^U(s), 0 \leq s \leq t\}. \quad (3.2)$$

Then $N(t)$ is a counting process with respect to this filtration in the sense of Definition A.5. It is also a right-continuous non-negative \mathcal{F}_t -submartingale. Thus, according to the Doob-Meyer Theorem, there exists a non-decreasing right-continuous \mathcal{F}_t -predictable compensator $A(t)$ such that $M(t) = N(t) - A(t)$ is an \mathcal{F}_t -martingale. The next theorem shows that under independent censoring condition we know the form of this compensator.

Theorem 3.2. *Let*

$$A(t) = \int_0^t Y(s) d\Lambda(s) = \Lambda(t \wedge X). \quad (3.3)$$

This is a right-continuous \mathcal{F}_t -predictable process. The process

$$M(t) = N(t) - A(t)$$

is an \mathcal{F}_t -martingale if and only if the independent censoring condition (3.1) holds. \diamond

Note.

- We will always assume that the independent censoring condition holds.
- Because $M(0) = 0$ a.s., we have $\mathbb{E} M(t) = 0$ and hence $\mathbb{E} N(t) = \mathbb{E} \Lambda(t \wedge X)$ for all $t > 0$.

Note. The claim of Theorem 3.2 can be extended to the case of multiple independent censored observations. Let $(T_1, C_1), \dots, (T_n, C_n)$ be independent, $X_i = T_i \wedge C_i$ and $\delta_i = \mathbb{1}(T_i \leq C_i)$. We observe independent pairs $(X_1, \delta_1), \dots, (X_n, \delta_n)$. Let $\Lambda_i(t)$ be the cumulative hazard of T_i . Let the independent censoring condition (3.1) hold for each pair (T_i, C_i) . Define $N_i(t) = \mathbb{1}(T_i \leq t, \delta_i = 1)$, $Y_i(t) = \mathbb{1}(X_i \geq t)$, and $N_i^U(t) = \mathbb{1}(C_i \leq t, \delta_i = 0)$. Define the extended filtration summarizing the history of observed failure and censoring times for all subjects up to time t :

$$\mathcal{F}_t = \sigma\{N_i(s), Y_i(s), 0 \leq s \leq t, i = 1, \dots, n\} = \sigma\{N_i(s), N_i^U(s), 0 \leq s \leq t, i = 1, \dots, n\}. \quad (3.4)$$

Let

$$A_i(t) = \int_0^t Y_i(s) d\Lambda_i(s) = \Lambda_i(t \wedge X_i). \quad (3.5)$$

Then $M_i(t) = N_i(t) - A_i(t)$ is a martingale with respect to the extended filtration (3.4).

It is easy to see that for a right-continuous martingale $M(t)$ such that $\mathbb{E} M^2(t) < \infty$, the process $M^2(t)$ is a right-continuous submartingale. The Doob-Meyer decomposition can be applied to M^2 , justifying the following corollary.

Corollary. For each right-continuous \mathcal{F}_t -martingale $M(t)$ with $E M^2(t) < \infty$ for all $t > 0$, there exists a non-decreasing right-continuous \mathcal{F}_t -predictable process $\langle M, M \rangle(t)$ with $\langle M, M \rangle(0) = 0$ and finite expectation such that

$$M^2(t) - \langle M, M \rangle(t) \quad \text{is an } \mathcal{F}_t\text{-martingale.}$$

The process $\langle M, M \rangle(t)$ is uniquely determined (up to sets of measure zero).

The process $\langle M, M \rangle$ introduced in the corollary is called *the predictable variation process*^{*} of the martingale $M(t)$.

Note. If $M(0) = 0$ a.s. and $E M^2(t) < \infty$ then $\text{var } M(t) = E M^2(t) = E \langle M, M \rangle(t)$.

The product of two martingales is not in general a submartingale, however, the Doob-Meyer theorem can be extended to guarantee the existence of a “pseudo-compensator” for martingale products.

Theorem 3.3. Let $M_1(t), M_2(t)$ be right-continuous \mathcal{F}_t -martingales with $E M_j^2(t) < \infty$ for all $t > 0, j = 1, 2$. Then there exists a process $\langle M_1, M_2 \rangle(t)$ with the following properties:

- (i) $\langle M_1, M_2 \rangle(t)$ is right-continuous, \mathcal{F}_t -predictable, $\langle M_1, M_2 \rangle(0) = 0$ a.s., and its expectation is finite $\forall t \geq 0$;
- (ii) $\langle M_1, M_2 \rangle(t)$ is a difference of two non-decreasing right-continuous \mathcal{F}_t -predictable processes;
- (iii)

$$M_1(t)M_2(t) - \langle M_1, M_2 \rangle(t) \quad \text{is an } \mathcal{F}_t\text{-martingale.} \quad \diamond$$

The process $\langle M_1, M_2 \rangle$ of the preceding theorem is called *the predictable covariation process*[†] of the martingales $M_1(t)$ and $M_2(t)$.

Note.

- If $M_1(0)$ and $M_2(0)$ are uncorrelated then $\text{cov}(M_1(t), M_2(t)) = E \langle M_1, M_2 \rangle(t)$.
- $M_1 M_2$ is a martingale if and only if $\langle M_1, M_2 \rangle(t) = 0$ at all $t \geq 0$. If this is the case, the martingales M_1 and M_2 are called *orthogonal*.

In the next section we will show that it is possible to derive explicit forms of predictable variation and covariation processes for counting process martingales.

*The end of
lecture 5
(Oct. 19)*

3.2. Martingale integrals

In this section, we consider processes of the type

$$L(t) = \int_0^t H(s) dM(s),$$

^{*} Český prediktabilní varianční proces [†] Český prediktabilní kovarianční proces

where H is a bounded \mathcal{F}_t -predictable process and M is an \mathcal{F}_t -martingale having paths with total variation bounded by a constant almost surely.

The results of this section are not formulated in their most general versions. They can be extended in several ways. First, to processes H that are only locally bounded: the details can be found in Fleming and Harrington (1991) and Andersen et al. (1993). Second, to martingales M that do not have paths of bounded variation such as the Brownian motion. This extension leads to Itô-type integrals.

Theorem 3.4. *Let N be a counting process and let A be its compensator according to Theorem 3.1 such that $M = N - A$ is an \mathcal{F}_t -martingale. Let $\Delta M(0) = 0$ a.s. Let H be a bounded \mathcal{F}_t -predictable process. Then*

$$L(t) = \int_0^t H(s) dM(s)$$

is an \mathcal{F}_t -martingale. ◇

Note.

- Since $L(0) = 0$ a.s., it follows that $E \int_0^t H(s) dM(s) = 0$ for all $t \geq 0$.
- Consider processes N_i, A_i, H_i for $i = 1, \dots, n$. Let $M_i = N_i - A_i$. Suppose that the conditions of Theorem 3.4 are satisfied for each i with a common filtration \mathcal{F}_t . Then

$$L(t) = \sum_{i=1}^n \int_0^t H_i(s) dM_i(s) \tag{3.6}$$

is an \mathcal{F}_t -martingale.

Now we consider predictable covariation processes for martingale integrals. When we write expressions such as $\int Z dX$ without limits and dummy arguments, they are to be interpreted as $\int_0^t Z(s) dX(s)$.

Theorem 3.5. *Let the conditions of Theorem 3.4 hold for $N_j, A_j, H_j, j = 1, 2$, take $M_j = N_j - A_j$ and assume $E M_j^2(t) < \infty$. Denote $L_j(t) = \int H_j dM_j$. Then there exists a predictable covariation process $\langle L_1, L_2 \rangle$ and*

$$\langle L_1, L_2 \rangle = \int H_1 H_2 d\langle M_1, M_2 \rangle.$$

In particular,

$$\int H_1 dM_1 \int H_2 dM_2 - \int H_1 H_2 d\langle M_1, M_2 \rangle$$

is an \mathcal{F}_t -martingale. ◇

Corollary.

- $\text{cov} \left(\int H_1 dM_1, \int H_2 dM_2 \right) = E \int H_1 H_2 d\langle M_1, M_2 \rangle$.
- If M_1 and M_2 are orthogonal then $\text{cov} \left(\int H_1 dM_1, \int H_2 dM_2 \right) = 0$ for any bounded predictable H_1 and H_2 .
- $\text{var} \int H dM = E \int H^2 d\langle M, M \rangle$.

Note. Let $U_1 = \sum_{i=1}^n \int H_i dM_i$ and $U_2 = \sum_{i=1}^n \int H_i^* dM_i$ with all H_i and H_i^* bounded and \mathcal{F}_t -predictable. Then $E U_1 = E U_2 = 0$,

$$\begin{aligned} \text{var } U_1 &= E \sum_{i=1}^n \sum_{j=1}^n \int H_i H_j d\langle M_i, M_j \rangle, \\ \text{var } U_2 &= E \sum_{i=1}^n \sum_{j=1}^n \int H_i^* H_j^* d\langle M_i, M_j \rangle, \quad \text{and} \\ \text{cov}(U_1, U_2) &= E \sum_{i=1}^n \sum_{j=1}^n \int H_i H_j^* d\langle M_i, M_j \rangle. \end{aligned}$$

When M_i and M_j are orthogonal martingales for all $i \neq j$, then

$$\begin{aligned} \text{var } U_1 &= E \sum_{i=1}^n \int H_i^2 d\langle M_i, M_i \rangle, \\ \text{var } U_2 &= E \sum_{i=1}^n \int (H_i^*)^2 d\langle M_i, M_i \rangle, \quad \text{and} \\ \text{cov}(U_1, U_2) &= E \sum_{i=1}^n \int H_i H_i^* d\langle M_i, M_i \rangle. \end{aligned}$$

These results will become useful when we learn how to calculate predictable variation and covariation processes.

Now consider a censored observation expressed as $N(t) = \mathbb{1}(T \leq t, \delta = 1)$ and $Y(t) = \mathbb{1}(X \geq t)$. Let the filtration be defined by (3.2). According to Theorem 3.2, $M(t) = N(t) - A(t)$ is an \mathcal{F}_t -martingale, where the compensator is $A(t) = \int_0^t Y(s) d\Lambda(s)$. In this setting, we are able to calculate the predictable variation process explicitly.

Theorem 3.6. Let $A(t) = \int_0^t Y(s) d\Lambda(s)$ be the compensator for the censored data counting process $N(t)$ and $M(t) = N(t) - A(t)$ the associated martingale. Then

$$\langle M, M \rangle(t) = \int_0^t [1 - \Delta A(s)] dA(s).$$

If the distribution of T is continuous then $\langle M, M \rangle(t) = A(t)$. ◇

For continuous failure times, the same process $A(t)$ compensates both $N(t)$ and $M^2(t)$.

Corollary. The martingale $M(t)$ is square integrable:

$$\text{var } M(t) = \mathbb{E} M^2(t) = \mathbb{E} \int_0^t (1 - \Delta A) dA \leq \mathbb{E} A(t) < \infty.$$

When T is continuous, $\text{var } M(t) = \mathbb{E} A(t) = \mathbb{E} N(t)$ at all $t \geq 0$.

Definition 3.2. Let $N_i(t)$, $i = 1, \dots, n$, be counting processes adapted to a common filtration \mathcal{F}_t . The collection $\{N_1(t), \dots, N_n(t)\}$ is called a *multivariate counting process** if and only if $\mathbb{P} [\Delta N_i(t) = 1, \Delta N_j(t) = 1] = 0$ for all $i \neq j$ and all $t \geq 0$. ∇

Note. Individual counting processes included in a multivariate counting process cannot jump at the same time. If failure times T_1, \dots, T_n are independent with continuous distributions, their counting processes $N_i(t) = \mathbb{1}(T_i \leq t, \delta_i = 1)$ form a multivariate counting process.

The next step is to calculate predictable covariation processes for certain special cases. The following theorem was proven in the course “Continuous Martingales and Counting Processes”.

Theorem 3.7. Let $\{N_1(t), \dots, N_n(t)\}$ be a multivariate counting process. Let A_i be a compensator for N_i , which is **continuous** for each $i = 1, \dots, n$, let $M_i = N_i - A_i$. Then $\langle M_i, M_j \rangle = 0$ a.s. for all $i \neq j$.

Note. If the underlying failure time variables are continuous, their martingales are orthogonal. The processes $M_i M_j$ are martingales for any $i \neq j$.

The previous theorem can be extended to any multivariate counting process.

Theorem 3.8. Let $\{N_1(t), \dots, N_n(t)\}$ be a multivariate counting process. Let A_i be a compensator for N_i , let $M_i = N_i - A_i$, $i = 1, \dots, n$. Then

$$\langle M_i, M_j \rangle = - \int \Delta A_i dA_j \quad \text{a.s. for all } i \neq j.$$

◇

Note. If the underlying failure time variables have discrete components so that their compensators have jumps, their martingales are negatively correlated. This agrees with the definition of the multivariate counting process, where jumps are prohibited for all other processes at the time when one of them jumps.

The last theorem does not require a multivariate counting process but makes a conditional independence assumption.

* Český mnohorozměrný čítací proces

Theorem 3.9. *Let $\Delta N_1(t), \dots, \Delta N_n(t)$ be independent given \mathcal{F}_{t-} . Then $\langle M_i, M_j \rangle(t) = 0$ almost surely for all $i \neq j$ and all $t \geq 0$.*

Let us summarize the important properties of martingale integral sums of the form (3.6) that we discovered in this section. Consider counting processes $N_i(t)$ and at-risk processes $Y_i(t)$, $i = 1, \dots, n$, that describe n independent observations of censored failure times with cumulative hazard functions Λ_i . Let $M_i(t) = N_i(t) - A_i(t)$, where $A_i(t) = \int_0^t Y_i(s) d\Lambda_i(s)$ is the compensator for $N_i(t)$ under independent censoring and a common filtration \mathcal{F}_t . By Theorem 3.6,

$$\langle M_i, M_i \rangle(t) = \int_0^t [1 - \Delta A_i(s)] dA_i(s) = \int_0^t [1 - \Delta \Lambda_i(s)] Y_i(s) d\Lambda_i(s).$$

For continuous failure times with hazard functions λ_i , we get $\langle M_i, M_i \rangle(t) = \int_0^t Y_i(s) \lambda_i(s) ds$. Also, $\langle M_i, M_j \rangle(t) = 0$ for all $i \neq j$ by Theorem 3.9 (because of independence).

Take $H_{ki}(t)$ bounded, \mathcal{F}_t -predictable processes $k = 1, 2$, $i = 1, \dots, n$. Consider the sums

$$U_k(t) = \sum_{i=1}^n \int_0^t H_{ki}(s) dM_i(s), \quad k = 1, 2.$$

We have established the following facts about these processes:

- $U_k(t)$ are \mathcal{F}_t -martingales by Theorem 3.4.
- $E U_k(t) = 0$.
- $\text{var } U_k(t) = \sum_{i=1}^n \int_0^t E [H_{ki}^2(s) Y_i(s)] [1 - \Delta \Lambda_i(s)] d\Lambda_i(s)$ by Theorems 3.5, 3.6, and 3.9.
- $\text{cov}(U_1(t), U_2(t)) = \sum_{i=1}^n \int_0^t E [H_{1i}(s) H_{2i}(s) Y_i(s)] [1 - \Delta \Lambda_i(s)] d\Lambda_i(s)$ by Theorems 3.5, 3.6, and 3.9.

3.3. Central limit theorems for sums of martingale integrals

In this section we introduce two central limit theorems for two different cases. Both assume a continuous failure time distribution, though they could be extended to discrete failure times as well.

Central limit theorem, case 1

We will be working under the following conditions:

- Let $\{N_{ki}^{(n)} : k = 1, \dots, r, i = 1, \dots, n\}$ be a multivariate counting process with respect to the stochastic basis $(\Omega, \mathcal{A}, \{\mathcal{F}_t\}_{t \geq 0}, P)$.
- Let the compensator $A_{ki}^{(n)}$ for $N_{ki}^{(n)}$ be continuous.

- Let $H_{ki}^{(n)}$, $k = 1, \dots, r$, $i = 1, \dots, n$, be bounded* \mathcal{F}_t -predictable processes on the interval $\langle 0, \tau \rangle$.

Let $M_{ki}^{(n)} = N_{ki}^{(n)} - A_{ki}^{(n)}$ be the \mathcal{F}_t -martingale for $N_{ki}^{(n)}$. Denote

$$U_{ki}^{(n)}(t) = \int_0^t H_{ki}^{(n)}(s) dM_{ki}^{(n)}(s) \quad \text{and} \quad U_k^{(n)}(t) = \sum_{i=1}^n U_{ki}^{(n)}(t).$$

Take any $\varepsilon > 0$ and denote

$$U_{ki,\varepsilon}^{(n)}(t) = \int_0^t H_{ki}^{(n)}(s) \mathbb{1}(|H_{ki}^{(n)}(s)| > \varepsilon) dM_{ki}^{(n)}(s) \quad \text{and} \quad U_{k,\varepsilon}^{(n)}(t) = \sum_{i=1}^n U_{ki,\varepsilon}^{(n)}(t).$$

All of these processes are square integrable martingales and, by Theorems 3.5, 3.6, and 3.7,

$$\langle U_k^{(n)}, U_k^{(n)} \rangle(t) = \sum_{i=1}^n \int_0^t [H_{ki}^{(n)}(s)]^2 dA_{ki}^{(n)}(s)$$

and

$$\langle U_{k,\varepsilon}^{(n)}, U_{k,\varepsilon}^{(n)} \rangle(t) = \sum_{i=1}^n \int_0^t [H_{ki}^{(n)}(s)]^2 \mathbb{1}(|H_{ki}^{(n)}(s)| > \varepsilon) dA_{ki}^{(n)}(s).$$

Theorem 3.10 (Central limit theorem I). *Let for all $t \in \langle 0, \tau \rangle$ and all $k = 1, \dots, r$*

$$\langle U_k^{(n)}, U_k^{(n)} \rangle(t) \xrightarrow{\mathbb{P}} \int_0^t f_k^2(s) ds < \infty$$

as $n \rightarrow \infty$, where f_k are non-negative measurable functions, and, for all $\varepsilon > 0$,

$$\langle U_{k,\varepsilon}^{(n)}, U_{k,\varepsilon}^{(n)} \rangle(t) \xrightarrow{\mathbb{P}} 0 \tag{3.7}$$

as $n \rightarrow \infty$. Then

$$(U_1^{(n)}, U_2^{(n)}, \dots, U_r^{(n)}) \Longrightarrow \left(\int f_1 dW_1, \int f_2 dW_2, \dots, \int f_r dW_r \right) \text{ on } D^r \langle 0, \tau \rangle,$$

where W_1, W_2, \dots, W_r are independent Brownian motions. \diamond

Note.

- The processes $\int f_k dW_k$, $k = 1, \dots, r$, are independent time-transformed Brownian motions. See Appendix A.3.
- The symbol “ \Longrightarrow ” means weak convergence of a multivariate stochastic process in the space $D^r \langle 0, \tau \rangle$ of left-continuous functions with right-hand limits defined on the r -dimensional Cartesian product of $\langle 0, \tau \rangle$. See Appendix A.4.

* Boundedness is not a necessary condition, it can be relaxed to *local boundedness*.

- The condition (3.7) is analogous to the Feller-Lindeberg condition for sums of random variables. It can be shown that it is automatically satisfied when both sequences $N_{k1}^{(n)}, \dots, N_{kn}^{(n)}$ and $A_{k1}^{(n)}, \dots, A_{kn}^{(n)}$ are identically distributed for each k .

The most important consequence of Theorem 3.10 is that the random vector of values $(U_1^{(n)}, U_2^{(n)}, \dots, U_r^{(n)})$ evaluated at a single fixed time $t \in \langle 0, \tau \rangle$ converges in distribution to an r -dimensional normal random vector with zero mean, independent components and variances $\int_0^t f_k^2(s) ds$.

The end of
lecture 7
(Oct. 26)

Central limit theorem, case 2

Now take a single set of counting processes with multiple integrands.

- Let $\{N_i^{(n)} : i = 1, \dots, n\}$ be a multivariate counting process with respect to the stochastic basis $(\Omega, \mathcal{A}, \{\mathcal{F}_t\}_{t \geq 0}, P)$.
- Let the compensator $A_i^{(n)}$ for $N_i^{(n)}$ be continuous.
- Let $H_{ki}^{(n)}$, $k = 1, \dots, r$, $i = 1, \dots, n$, be bounded* \mathcal{F}_t -predictable processes on the interval $\langle 0, \tau \rangle$.

Let $M_i^{(n)} = N_i^{(n)} - A_i^{(n)}$ be the \mathcal{F}_t -martingale for $N_i^{(n)}$. Denote

$$U_{ki}^{(n)}(t) = \int_0^t H_{ki}^{(n)}(s) dM_i^{(n)}(s) \quad \text{and} \quad U_k^{(n)}(t) = \sum_{i=1}^n U_{ki}^{(n)}(t).$$

Take any $\varepsilon > 0$ and denote

$$U_{ki,\varepsilon}^{(n)}(t) = \int_0^t H_{ki}^{(n)}(s) \mathbb{1}(|H_{ki}^{(n)}(s)| > \varepsilon) dM_i^{(n)}(s) \quad \text{and} \quad U_{k,\varepsilon}^{(n)}(t) = \sum_{i=1}^n U_{ki,\varepsilon}^{(n)}(t).$$

All of these processes are square integrable martingales and, by Theorems 3.5, 3.6, and 3.7,

$$\langle U_k^{(n)}, U_l^{(n)} \rangle(t) = \sum_{i=1}^n \int_0^t H_{ki}^{(n)}(s) H_{li}^{(n)}(s) dA_i^{(n)}(s)$$

and

$$\langle U_{k,\varepsilon}^{(n)}, U_{l,\varepsilon}^{(n)} \rangle(t) = \sum_{i=1}^n \int_0^t H_{ki}^{(n)}(s) H_{li}^{(n)}(s) \mathbb{1}(|H_{ki}^{(n)}(s)| > \varepsilon) \mathbb{1}(|H_{li}^{(n)}(s)| > \varepsilon) dA_i^{(n)}(s).$$

Theorem 3.11 (Central limit theorem II). Let for all $t \in \langle 0, \tau \rangle$ and all $k, l = 1, \dots, r$

$$\langle U_k^{(n)}, U_l^{(n)} \rangle(t) \xrightarrow{P} c_{kl}(t) < \infty$$

* Again, boundedness can be relaxed.

3. Counting Processes and Martingales

as $n \rightarrow \infty$, where c_{kl} are continuous functions, and, for all $\varepsilon > 0$ and all $k = 1, \dots, r$,

$$\langle U_{k,\varepsilon}^{(n)}, U_{k,\varepsilon}^{(n)} \rangle(t) \xrightarrow{\mathbb{P}} 0$$

as $n \rightarrow \infty$. Then

$$(U_1^{(n)}, U_2^{(n)}, \dots, U_r^{(n)}) \Longrightarrow (W_1^*, \dots, W_r^*) \text{ on } D^r \langle 0, \tau \rangle,$$

where W_1^*, \dots, W_r^* are dependent zero-mean Gaussian processes with independent increments, a.s. continuous sample paths, and covariance functions $\text{cov}(W_k^*(s), W_l^*(t)) = c_{kl}(s)$ for all k, l and all $0 \leq s \leq t \leq \tau$. \diamond

By this theorem, the random vector $(U_1^{(n)}, U_2^{(n)}, \dots, U_r^{(n)})$ evaluated at a single fixed time $t \in \langle 0, \tau \rangle$ converges in distribution to an r -dimensional normal random vector with zero mean and covariance matrix $c_{kl}(t)$, $k, l \in 1, \dots, r$.

4. Nonparametric Estimation of Failure Time Distribution

4.1. Estimating cumulative hazard function and survival function

Let $(T_1, C_1), \dots, (T_n, C_n)$ be independent, let T_1, \dots, T_n be identically distributed with survival function S and cumulative hazard function Λ .

Let $X_i = T_i \wedge C_i$ be censored failure times and $\delta_i = \mathbb{1}(T_i \leq C_i)$ failure indicators. We would like to estimate the survival function S and the cumulative hazard function Λ from the independent observations $(X_1, \delta_1), \dots, (X_n, \delta_n)$ without making any assumptions on the distribution of T_i .

If the data were not censored, the survival function S could be estimated by $\widehat{S} = 1 - \widehat{F}$, where $\widehat{F}(t) = n^{-1} \sum_{i=1}^n \mathbb{1}(T_i \leq t)$ is the empirical distribution function. So our task can be viewed as extending the empirical distribution function to censored data.

Consider the counting processes $N_i(t) = \mathbb{1}(T_i \leq t, \delta_i = 1)$ and at-risk processes $Y_i(t) = \mathbb{1}(X_i \geq t)$, $i = 1, \dots, n$. Take the extended filtration

$$\mathcal{F}_t = \sigma\{N_i(u), Y_i(u), 0 \leq u \leq t, i = 1, \dots, n\}$$

and the compensator $A_i(t) = \int_0^t Y_i(u) d\Lambda(u)$. If the independent censoring condition (3.1) holds (we always assume this) for each pair (T_i, C_i) the process $M_i(t) = N_i(t) - A_i(t)$ is an \mathcal{F}_t -martingale (see Section 3.1 on p. 19).

Let $\overline{N}(t) = \sum_{i=1}^n N_i(t)$ and $\overline{Y}(t) = \sum_{i=1}^n Y_i(t)$. It follows that $\overline{M}(t) = \sum_{i=1}^n M_i(t) = \overline{N}(t) - \int_0^t \overline{Y}(u) d\Lambda(u)$ is an \mathcal{F}_t -martingale.

Denote by T_* the time when the data run out, i.e., $T_* = \inf\{s : \overline{Y}(s) = 0\}$. Take the bounded \mathcal{F}_t -predictable process

$$H(u) = \frac{\mathbb{1}(\overline{Y}(u) > 0)}{\overline{Y}(u)}.$$

For $u \geq T_*$, the numerator is 0 and the whole process is defined as 0. By Theorem 3.4, $\int H d\overline{M}$ is a martingale and its expectation is zero. Write

$$\int_0^t H(u) d\overline{M}(u) = \int_0^t \frac{\mathbb{1}(\overline{Y}(u) > 0)}{\overline{Y}(u)} d\overline{N}(u) - \int_0^t \mathbb{1}(\overline{Y}(u) > 0) d\Lambda(u) = \int_0^t \frac{d\overline{N}(u)}{\overline{Y}(u)} - \Lambda(t \wedge T_*).$$

The left-hand side has zero expectation. The random part of the right-hand side appears to be a good candidate for an unbiased estimator of $\Lambda(t)$ at times t when data are still observed.

Definition 4.1. The function

$$\widehat{\Lambda}(t) = \int_0^t \frac{d\overline{N}(u)}{\overline{Y}(u)}$$

is called the *Nelson-Aalen estimator* of the cumulative hazard function. ∇

Note.

- This estimator was proposed by Nelson (1969). Its consistency and weak convergence were first proven by Breslow and Crowley (1974) using standard methods and then by Aalen (1978) using martingale theory.
- The Nelson-Aalen estimator is constant for $t \geq T_*$. There is no information in the data about the hazard after the last observation fails or is censored.
- Denote by $t_1 < \dots < t_d$ the ordered distinct failure times observed in the data. Then

$$\widehat{\Lambda}(t) = \sum_{\{j:t_j \leq t\}} \frac{\Delta N(t_j)}{\overline{Y}(t_j)} = \sum_{\{j:t_j \leq t\}} \widehat{\lambda}_j.$$

This is how the estimator is calculated. The contribution $\widehat{\lambda}_j$ is an empirical estimate of the discrete hazard at t_j : the ratio of the number of subjects who failed at t_j divided by the number of subjects who could have failed at t_j .

Having an estimator $\widehat{\Lambda}$ for Λ , we can use it to obtain an estimator for the survival function S . By equation (1.2), we have $S(t) = e^{-\Lambda(t)}$ for continuous failure time distributions. So we could take

$$\widehat{S}(t) = e^{-\widehat{\Lambda}(t)}.$$

This is called the *Fleming-Harrington estimator* of survival function. However, (1.2) only holds for continuous failure time distributions, which allow no ties among failure times. So let us use equality (1.1) instead, which is more universal and can be transformed into the relationship

$$S(t) = 1 - \int_0^t S(u-) d\Lambda(u).$$

Plug in the Nelson-Aalen estimator and define an estimator of survival function by the equation

$$\widehat{S}(t) = 1 - \int_0^t \widehat{S}(u-) d\widehat{\Lambda}(u).$$

This equation can be solved recursively, leading to the following definition.

*The end of
lecture 8
(Oct. 31)*

Definition 4.2. The function

$$\widehat{S}(t) = \prod_{u \leq t} \left[1 - \frac{\Delta \bar{N}(u)}{\bar{Y}(u)} \right]$$

is called the *Kaplan-Meier estimator* of survival function. ▽

Note.

- This estimator was first proposed by Kaplan and Meier (1958).
- With $t_1 < \dots < t_d$ the ordered distinct failure times,

$$\widehat{S}(t) = \prod_{\{j: t_j \leq t\}} \left[1 - \frac{\Delta \bar{N}(t_j)}{\bar{Y}(t_j)} \right] = \prod_{\{j: t_j \leq t\}} (1 - \widehat{\lambda}_j).$$

The last expression agrees with equation (1.3) for discrete hazard functions.

- The Kaplan-Meier estimator is a right-continuous piecewise constant function. When the data are not censored, $1 - \widehat{S}$ equals the empirical distribution function.
- The Kaplan-Meier estimator is constant for $t \geq T_*$. It does not drop to zero at the last observed failure time t_d unless all the remaining subjects fail at that time.

4.2. Properties of the Nelson-Aalen estimator

Select $\tau > 0$ a fixed time such that $P[Y_i(\tau) = 1] > \delta > 0$ for all $i = 1, \dots, n$ and $\Lambda(\tau) < \infty$. If the data $N_i(t), Y_i(t)$ are identically distributed (i.e., censoring times are), then there exists a function $\pi(t) = P[Y_i(t) = 1]$ which is positive on $\langle 0, \tau \rangle$. By the weak law of large numbers, it can be consistently estimated by $\bar{Y}(t)/n$. The next lemma shows that the consistency holds uniformly on $\langle 0, \tau \rangle$.

Lemma 4.1. *If the data are independent and identically distributed, then*

$$\sup_{t \in \langle 0, \tau \rangle} \left| \frac{1}{n} \bar{Y}(t) - \pi(t) \right| \xrightarrow{P} 0. \quad (4.1)$$

◇

If the censoring times are not identically distributed, then we assume that there exists a function π which satisfies (4.1).

As shown previously, the Nelson-Aalen estimator $\widehat{\Lambda}(t) = \int_0^t \frac{d\bar{N}(u)}{\bar{Y}(u)}$ can be written as

$$\widehat{\Lambda}(t) = \Lambda^*(t) + \int_0^t H(u) d\bar{M}(u),$$

where $H(u) = \mathbb{1}(\bar{Y}(u) > 0)/\bar{Y}(u)$ is predictable and $\Lambda^*(t) = \Lambda(t \wedge T_*)$. This martingale representation together with the results of Chapter 3 justifies the following theorem.

Theorem 4.2.

- (i) For any $t \in \langle 0, \tau \rangle$, $E [\widehat{\Lambda}(t) - \Lambda^*(t)] = 0$.
- (ii) For any $t \in \langle 0, \tau \rangle$, $0 \geq E [\widehat{\Lambda}(t) - \Lambda(t)] \geq -[1 - \pi(t)]^n \Lambda(t) \rightarrow 0$ as $n \rightarrow \infty$, where the rightmost inequality holds only for identically distributed data.
- (iii) Denote $\text{var } \sqrt{n} [\widehat{\Lambda}(t) - \Lambda^*(t)]$ by $\sigma_\Lambda^2(t)$. Then

$$\sigma_\Lambda^2(t) = \int_0^t n E H(u) [1 - \Delta\Lambda(u)] d\Lambda(u).$$

- (iv) If Λ is continuous with hazard function λ ,

$$\sqrt{n} [\widehat{\Lambda}(t) - \Lambda(t)] \Rightarrow \int_0^t \sqrt{\frac{\lambda(u)}{\pi(u)}} dW(u) \quad \text{on } D\langle 0, \tau \rangle. \quad \diamond$$

Note.

- Part (iv) of Theorem 4.2 implies that for any fixed $t \in \langle 0, \tau \rangle$, $\sqrt{n} [\widehat{\Lambda}(t) - \Lambda(t)]$ has asymptotically normal distribution with zero mean and variance

$$\int_0^t \frac{\lambda(u)}{\pi(u)} du = \lim_{n \rightarrow \infty} \sigma_\Lambda^2(t).$$

- Part (iv) of Theorem 4.2 implies uniform consistency, i.e.

$$\sup_{t \in \langle 0, \tau \rangle} |\widehat{\Lambda}(t) - \Lambda(t)| \xrightarrow{P} 0 \quad \text{as } n \rightarrow \infty.$$

The next theorem introduces a variance estimator for $\widehat{\Lambda}(t)$ and establishes its consistency and unbiasedness.

*The end of
lecture 9
(Nov. 2)*

Theorem 4.3. Define

$$S_\Lambda^2(t) = \int_0^t \frac{\mathbb{1}(\bar{Y}(u) > 0)}{\bar{Y}^2(u)} \left[1 - \frac{\Delta\bar{N}(u) - 1}{\bar{Y}(u) - 1} \right] d\bar{N}(u).$$

Then

$$nS_\Lambda^2(t) \xrightarrow{P} \int_0^t \frac{1}{\pi(u)} [1 - \Delta\Lambda(u)] d\Lambda(u)$$

and

$$E [S_\Lambda^2(t) - n^{-1} \sigma_\Lambda^2(t)] = \int_0^t P [\bar{Y}(u) = 1] \Delta\Lambda(u) d\Lambda(u),$$

which is equal to zero if the failure time distribution is continuous. ◇

4.3. Properties of the Kaplan-Meier estimator

Let us return to the Kaplan-Meier estimator of survival function

$$\widehat{S}(t) = \prod_{u \leq t} \left[1 - \frac{\Delta \bar{N}(u)}{\bar{Y}(u)} \right].$$

The following two lemmas provide representations of this estimator that are useful for investigating its properties.

Lemma 4.4. *At all $t \geq 0$ such that $S(t) > 0$, it holds*

$$\frac{\widehat{S}(t)}{S(t)} = 1 - \int_0^t \frac{\widehat{S}(u-)}{S(u)} d(\widehat{\Lambda} - \Lambda)(u). \quad \diamond$$

Lemma 4.5. *At all $t \geq 0$ such that $S(t) > 0$, it holds*

$$\frac{\widehat{S}(t) - S(t)}{S(t)} = - \int_0^t H(u) d\bar{M}(u) + B(t),$$

where

$$H(u) = \frac{\widehat{S}(u-)}{S(u)} \frac{\mathbb{1}(\bar{Y}(u) > 0)}{\bar{Y}(u)}$$

is a predictable process and

$$B(t) = \frac{\widehat{S}(T^*)}{S(T^*)} \frac{S(T^*) - S(t)}{S(t)} \mathbb{1}(T^* < t). \quad \diamond$$

For $t \leq \tau$, $B(t) \xrightarrow{P} 0$ because $P[T^* > t] \rightarrow 1$.

The next theorem specifies the first two moments of the Kaplan-Meier estimator.

Theorem 4.6. *At all $t \geq 0$ such that $S(t) > 0$, it holds*

(i)

$$E \widehat{S}(t) = S(t) + E \mathbb{1}(T^* > t) \frac{\widehat{S}(T^*)}{S(T^*)} [S(T^*) - S(t)] \geq S(t)$$

(ii) *If C_1, \dots, C_n are identically distributed then*

$$E \widehat{S}(t) - S(t) \leq [1 - S(t)] [1 - \pi(t)]^n \rightarrow 0.$$

(iii)

$$\begin{aligned} \text{var} [\widehat{S}(t) - S(t)B(t)] &= S^2(t) \int_0^\tau E \frac{\widehat{S}^2(u-)}{S^2(u)} \frac{\mathbb{1}(\bar{Y}(u) > 0)}{\bar{Y}(u)} [1 - \Delta \Lambda(u)] d\Lambda(u) \\ &= \text{var} \widehat{S}(t) + o(1). \end{aligned} \quad \diamond$$

*The end of
lecture 10
(Nov. 7)*

Note. An estimator for $\text{var} \sqrt{n}[\widehat{S}(t) - S(t)]$ can be obtained from item (iii) of the previous theorem by replacing S with \widehat{S} and Λ with $\widehat{\Lambda}$. This gives

$$\widehat{V}(t) = n\widehat{S}^2(t) \int_0^t \frac{d\overline{N}(u)}{[\overline{Y}(u) - \Delta\overline{N}(u)]\overline{Y}(u)} \equiv \widehat{S}^2(t)\widehat{\sigma}(t). \quad (4.2)$$

This is called *the Greenwood formula* for estimating the variance of the Kaplan-Meier estimator.

Proposition 4.7. *Let the observations be independent and identically distributed and Λ be continuous. Then*

$$\sup_{0 \leq t \leq \tau} |\widehat{S}(t) - S(t)| \xrightarrow{P} 0. \quad \diamond$$

The previous proposition establishes the uniform consistency of the Kaplan-Meier estimator. We proceed to claim weak convergence to a zero-mean Gaussian process.

Theorem 4.8. *Let the observations be independent and identically distributed and Λ be continuous and differentiable almost everywhere with hazard function $\Lambda' = \lambda$. Denote $\sigma(t) = \int_0^t \pi^{-1}(s)\lambda(s) ds$. Then*

(i)

$$\sqrt{n}[\widehat{S}(t) - S(t)] \Rightarrow S(t)W(\sigma(t)) \quad \text{on } D\langle 0, \tau \rangle,$$

$$\text{where } W(\sigma(t)) = \int_0^t \sqrt{\frac{\lambda(s)}{\pi(s)}} dW(s).$$

(ii)

$$\sqrt{n} \frac{\widehat{S}(t) - S(t)}{\widehat{S}(t)} \Rightarrow W(\sigma(t)) \quad \text{on } D\langle 0, \tau \rangle. \quad \diamond$$

This theorem was first proven by Breslow and Crowley (1974) under somewhat stronger conditions.

Corollary. For a fixed time t in $\langle 0, \tau \rangle$, $\sqrt{n}[\widehat{S}(t) - S(t)] \xrightarrow{D} N(0, V(t))$, where

$$V(t) = S^2(t)\sigma(t) = S^2(t) \int_0^t \pi^{-1}(s)\lambda(s) ds.$$

Note. The Greenwood formula $\widehat{V}(t)$ introduced in (4.2) is a uniformly consistent estimator for $V(t)$ on $\langle 0, \tau \rangle$.

4.4. Confidence bounds for survival function

It is easy to construct pointwise confidence intervals for $S(t)$ at a fixed $t \in \langle 0, \tau \rangle$. Based on corollary to Theorem 4.8 and using the Greenwood formula, we get

$$P \left[\widehat{S}(t) - u_{1-\alpha/2} \sqrt{\frac{\widehat{V}(t)}{n}} < S(t) < \widehat{S}(t) + u_{1-\alpha/2} \sqrt{\frac{\widehat{V}(t)}{n}} \right] \rightarrow 1 - \alpha.$$

The lower and upper bounds of a confidence interval for $S(t)$ with asymptotic coverage probability $1 - \alpha$ are

$$\widehat{S}(t) \left(1 - u_{1-\alpha/2} \sqrt{\frac{\widehat{\sigma}(t)}{n}} \right) \quad \text{and} \quad \widehat{S}(t) \left(1 + u_{1-\alpha/2} \sqrt{\frac{\widehat{\sigma}(t)}{n}} \right),$$

respectively.

Let us turn our attention to confidence bounds that cover the whole curve with the desired probability, not just at one point. We are looking for random functions $C_L(t)$ and $C_U(t)$ calculated from the data such that

$$P [C_L(t) < S(t) < C_U(t) \text{ for all } t \in \langle 0, \tau \rangle] \rightarrow 1 - \alpha.$$

The following lemma is based on Theorem 4.8, point (ii), and the continuous mapping theorem for weak convergence (see the note on p. 52 in the Appendix).

Lemma 4.9. *Under the conditions of Theorem 4.8,*

$$\sqrt{\frac{n}{\widehat{\sigma}(\tau)}} \sup_{t \in \langle 0, \tau \rangle} \frac{1}{\widehat{S}(t)} |\widehat{S}(t) - S(t)| \xrightarrow{D} \sup_{0 \leq u \leq 1} |W(u)|.$$

◇

*The end of
lecture 11
(Nov. 14)*

The distribution function of the limiting random variable can be expressed as

$$P \left[\sup_{0 \leq u \leq 1} |W(u)| \leq y \right] = \frac{4}{\pi} \sum_{k=0}^{\infty} \frac{(-1)^k}{2k+1} \exp \left\{ -\frac{\pi^2 (2k+1)^2}{8y^2} \right\}$$

for any $y > 0$ (Billingsley 1999). Denote by c_α the α -quantile of this distribution.

Based on this result, Gill (1980) proposed asymptotic confidence bounds for the whole survival curve on the interval $\langle 0, \tau \rangle$ with lower and upper boundaries

$$\widehat{S}(t) \left(1 - c_{1-\alpha} \sqrt{\frac{\widehat{\sigma}(\tau)}{n}} \right) \quad \text{and} \quad \widehat{S}(t) \left(1 + c_{1-\alpha} \sqrt{\frac{\widehat{\sigma}(\tau)}{n}} \right).$$

Notice that the Gill bounds differ from the pointwise confidence intervals not only by the quantile but also by using $\widehat{\sigma}(\tau)$ in place of $\widehat{\sigma}(t)$.

The Gill bounds have a relatively large width at t close to zero when $\widehat{S}(t) \approx 1$. To overcome this shortcoming, alternative bounds were proposed by Hall and Wellner (1980). They are based on the following extension of Theorem 4.8.

4. Nonparametric Estimation of Failure Time Distribution

Theorem 4.10. Let $K(t) = \frac{\sigma(t)}{1+\sigma(t)}$ and $\widehat{K}(t) = \frac{\widehat{\sigma}(t)}{1+\widehat{\sigma}(t)}$. Under the conditions of Theorem 4.8,

$$\sqrt{n} \frac{1 - \widehat{K}(t)}{\widehat{S}(t)} [\widehat{S}(t) - S(t)] \implies B(K(t)) \quad \text{on } D\langle 0, \tau \rangle. \quad \diamond$$

Here, the process $B(t)$ is Brownian bridge discussed in Appendix A.3.3 on p. 50. It is a Gaussian process defined on the interval $\langle 0, 1 \rangle$, with zero mean, variance function $t(1 - t)$, and covariance function at $s \leq t$ given by $s(1 - t)$. Notice that $K(t) \in \langle 0, 1 \rangle$ and $\widehat{K}(t) \in \langle 0, 1 \rangle$. The limiting process is a time-transformed Brownian bridge, with $K(t)$ playing the role of a non-decreasing time transformation from $\langle 0, \tau \rangle$ to $\langle 0, 1 \rangle$.

It follows from Theorem 4.10 and the continuous mapping theorem A.2 that

$$\mathbb{P} \left[\sup_{0 \leq t \leq \tau} \sqrt{n} \frac{1 - \widehat{K}(t)}{\widehat{S}(t)} |\widehat{S}(t) - S(t)| \geq y \right] \xrightarrow{D} \mathbb{P} \left[\sup_{0 \leq t \leq \tau} |B(K(t))| \geq y \right]$$

We have

$$\mathbb{P} \left[\sup_{0 \leq t \leq \tau} |B(K(t))| \geq y \right] = \mathbb{P} \left[\sup_{0 \leq u \leq K^{-1}(\tau)} |B(u)| \geq y \right]$$

Denote the α -quantile of the distribution of $\sup_{0 \leq u \leq K^{-1}(\tau)} |B(u)|$ by $k_\alpha(\tau)$. This can be calculated numerically.

The Hall-Wellner confidence bounds for survival function have lower and upper boundaries

$$\widehat{S}(t) \left(1 - k_{1-\alpha}(\tau) \frac{1}{\sqrt{n}[1 - \widehat{K}(t)]} \right) \quad \text{and} \quad \widehat{S}(t) \left(1 + k_{1-\alpha}(\tau) \frac{1}{\sqrt{n}[1 - \widehat{K}(t)]} \right).$$

Using the relationship $\frac{1}{1 - \widehat{K}(t)} = 1 + \widehat{\sigma}(t)$, we can rewrite the Hall-Wellner bounds as

$$\widehat{S}(t) \left(1 - k_{1-\alpha}(\tau) \frac{1 + \widehat{\sigma}(t)}{\sqrt{n}} \right) \quad \text{and} \quad \widehat{S}(t) \left(1 + k_{1-\alpha}(\tau) \frac{1 + \widehat{\sigma}(t)}{\sqrt{n}} \right).$$

We can get conservative Hall-Wellner bounds that do not require the calculation of $k_{1-\alpha}(\tau)$ for a specific τ as follows: Since

$$\mathbb{P} \left[\sup_{0 \leq u \leq K^{-1}(\tau)} |B(u)| \geq y \right] \leq \mathbb{P} \left[\sup_{0 \leq u \leq 1} |B(u)| \geq y \right] = 2 \sum_{j=1}^{\infty} (-1)^{j+1} e^{-2j^2 y^2},$$

where the distribution on the right-hand side can be calculated (Billingsley 1999) and is the same as the asymptotic distribution of the Kolmogorov-Smirnov test statistic, we can replace $k_{1-\alpha}(\tau)$ by the critical value of the Kolmogorov-Smirnov test $k_{1-\alpha}$ to obtain confidence bounds with asymptotic coverage $\geq 1 - \alpha$.

5. Two-Sample Tests for Censored Data

5.1. Notation

Consider two independent samples of censored data obtained from two groups of subjects. We assume that (T_{ki}, C_{ki}) , $i = 1, \dots, n_k$, $k = 1, 2$, are independent random vectors. Let T_{k1}, \dots, T_{kn_k} be identically distributed with survival function S_k and cumulative hazard function Λ_k , $k = 1, 2$. The goal is to test whether the failure time distributions in the two groups are the same. In particular,

$$H_0 : S_1(t) = S_2(t) \text{ for all } t \geq 0 \quad \text{against} \quad H_1 : \text{There exists } t \geq 0 \text{ s.t. } S_1(t) \neq S_2(t).$$

Of course, the hypothesis can be equivalently formulated as equality of cumulative hazard functions.

Denote $X_{ki} = T_{ki} \wedge C_{ki}$ censored failure times and $\delta_{ki} = \mathbb{1}(T_{ki} \leq C_{ki})$ failure indicators. The observed data are (X_{ki}, δ_{ki}) , $i = 1, \dots, n_k$, $k = 1, 2$. The observed data can be also expressed in terms of counting processes $N_{ki}(t) = \mathbb{1}(T_{ki} \leq t, \delta_{ki} = 1)$ and at-risk processes $Y_{ki}(t) = \mathbb{1}(X_{ki} \geq t)$, $i = 1, \dots, n_k$, $k = 1, 2$.

We will work with the filtration

$$\mathcal{F}_t = \sigma\{N_{ki}(u), Y_{ki}(u), 0 \leq u \leq t, i = 1, \dots, n_k, k = 1, 2\}.$$

Take the compensator $A_{ki}(t) = \int_0^t Y_{ki}(u) d\Lambda_k(u)$. Under the independent censoring condition, $M_{ki}(t) = N_{ki}(t) - A_{ki}(t)$ are all \mathcal{F}_t -martingales. Define $\bar{N}_k(t) = \sum_{i=1}^{n_k} N_{ki}(t)$ and $\bar{Y}_k(t) = \sum_{i=1}^{n_k} Y_{ki}(t)$. Then $\bar{M}_k(t) = \sum_{i=1}^{n_k} M_{ki}(t) = \bar{N}_k(t) - \int_0^t \bar{Y}_k(u) d\Lambda_k(u)$ are \mathcal{F}_t -martingales, $k = 1, 2$. Also define $\bar{N}(t) = \bar{N}_1(t) + \bar{N}_2(t)$ and $\bar{Y}(t) = \bar{Y}_1(t) + \bar{Y}_2(t)$.

*The end of
lecture 12
(Nov. 21)*

5.2. Heuristic derivation of the logrank test

Take all distinct failure times observed in both groups and order them. Denote the ordered failure times $t_1 < t_2 < \dots < t_d$. Denote the number of observed failures in the k -th group at the time t_j by $D_{kj} = \Delta \bar{N}_k(t_j)$ and the number of subjects at risk in the k -th group at the time t_j by $R_{kj} = \bar{Y}_k(t_j)$. Let $D_j = D_{1j} + D_{2j}$ and $R_j = R_{1j} + R_{2j}$ be the number of failures and the risk set size in the combined sample. With this notation, the data observed at the time t_j can be summarized in the form of a two-way contingency table, see Table 5.1.

Table 5.1.: Contingency table of failing and non-failing subjects in the two groups at the j -th ordered failure time.

Failure	Group 1	Group 2	Total
Yes	D_{1j}	D_{2j}	D_j
No	$R_{1j} - D_{1j}$	$R_{2j} - D_{2j}$	$R_j - D_j$
Total	R_{1j}	R_{2j}	R_j

If H_0 is true then the probabilities of failing at the time t_j (conditional on being at risk at this time) are the same in both groups. Denote them by π_j . Given R_{1j} , the number D_{1j} of failures in the first group has a binomial distribution $\text{Bi}(R_{1j}, \pi_j)$. Similarly, $D_{2j} \sim \text{Bi}(R_{2j}, \pi_j)$. Conditionally on the marginals D_j , R_{1j} , and R_{2j} , the number D_{1j} of failures in the first group has a hypergeometric distribution under H_0 . Thus, conditionally on D_j , R_{1j} , and R_{2j} ,

$$E D_{1j} = D_j \frac{R_{1j}}{R_j} \equiv E_j$$

and $\text{var } D_{1j} = D_j \frac{R_{1j} R_{2j}}{R_j^2} \frac{R_j - D_j}{R_j - 1} \equiv V_j,$

if H_0 holds. The test statistic will compare the number of failures observed in the first group with the conditional expectation under H_0 at each failure time, and accumulate these contributions. Thus,

$$W = \sum_{j=1}^d (D_{1j} - E_j) = \sum_{j=1}^d \left(D_{1j} - D_j \frac{R_{1j}}{R_j} \right). \quad (5.1)$$

To standardize this, we divide W by $\sqrt{\widehat{\text{var}} W}$, the estimated standard deviation of W . If W were the sum of independent terms, we could take $\widehat{\text{var}} W = \sum_{j=1}^d V_j$. Unfortunately, $D_{1j} - E_j$ are clearly not independent. Nevertheless, it can be shown that

$$\frac{\sum_{j=1}^d (D_{1j} - E_j)}{\sqrt{\sum_{j=1}^d V_j}} \xrightarrow{D} N(0, 1) \quad (5.2)$$

under H_0 . Thus, we reject H_0 when

$$\frac{\left| \sum_{j=1}^d (D_{1j} - E_j) \right|}{\sqrt{\sum_{j=1}^d V_j}} \geq u_{1-\alpha/2} \quad \text{or} \quad \frac{[\sum_{j=1}^d (D_{1j} - E_j)]^2}{\sum_{j=1}^d V_j} \geq \chi_1^2(1 - \alpha/2).$$

This test is called the two-sample *logrank test*. It was proposed (without any proof of its properties) by Mantel (1966).

We will prove (5.2) using martingale theory. In order to do that, we need to write the numerator of the logrank test statistic as a difference of stochastic integrals. Recall that $D_{kj} = \Delta \bar{N}_k(t_j)$ and $R_{kj} = \bar{Y}_k(t_j)$ and express (5.1) as follows:

$$\begin{aligned} W &= \int_0^\infty 1 d\bar{N}_1(s) - \int_0^\infty \frac{\bar{Y}_1(s)}{\bar{Y}(s)} d(\bar{N}_1 + \bar{N}_2)(s) \\ &= \int_0^\infty \left(1 - \frac{\bar{Y}_1(s)}{\bar{Y}(s)}\right) \bar{Y}_1(s) \frac{d\bar{N}_1(s)}{\bar{Y}_1(s)} - \int_0^\infty \frac{\bar{Y}_1(s)}{\bar{Y}(s)} \bar{Y}_2(s) \frac{d\bar{N}_2(s)}{\bar{Y}_2(s)} \\ &= \int_0^\infty \frac{\bar{Y}_1(s)\bar{Y}_2(s)}{\bar{Y}(s)} d(\hat{\Lambda}_1 - d\hat{\Lambda}_2)(s), \end{aligned}$$

where $\hat{\Lambda}_k(t) = \int_0^t \frac{d\bar{N}_k(s)}{\bar{Y}_k(s)}$ is the Nelson-Aalen estimator of the cumulative hazard for the k -th group.

This also shows that W is the integrated weighted difference between the Nelson-Aalen estimators of cumulative hazards in the two groups. The weight $\bar{Y}_1(s)\bar{Y}_2(s)/\bar{Y}(s)$ takes into account the number of subjects that are observed at both groups at the time s . When either of the groups runs out of observations ($\bar{Y}_k = 0$), the weight is zero.

5.3. Linear rank statistics for censored data, weighted logrank tests

Definition, connections to rank tests

We will consider a class of test statistics of the form

$$W_K = \int_0^\infty K(s) d(\hat{\Lambda}_1 - d\hat{\Lambda}_2)(s),$$

where $K(s)$ is a bounded non-negative predictable process such that $K(s) = 0$ whenever $\bar{Y}_1(s) = 0$ or $\bar{Y}_2(s) = 0$. Every process $K(s)$ with these properties can be written in the form

$$K(s) = \sqrt{\frac{n_1 + n_2}{n_1 n_2}} W(s) \frac{\bar{Y}_1(s)\bar{Y}_2(s)}{\bar{Y}(s)},$$

where $W(s)$ is a bounded non-negative predictable process. The logrank test is obtained by setting $W(s) \equiv 1$. The statistics W_K are called a *weighted logrank statistics*. In the notation of equation (5.1), a weighted logrank statistic can be expressed as

$$W_K = \sum_{j=1}^d W_j \left(D_{1j} - D_j \frac{R_{1j}}{R_j} \right),$$

where $W_j = W(t_j)$ is a weight for the j -th observed failure time.

We require the process W to be predictable, which implies that $W(s)$ must not depend on the data observed after s . If we choose $W(s)$ so that it depends only on the observed

numbers of failures before s and numbers of subjects who were at risk when those failures occurred (but not on failure and censoring times directly), the statistic W_K becomes invariant with respect to strictly increasing transformations of time (they do not change the order of the observed failure or censoring times). Because of this, W_K represents a class of *linear rank statistics* for censored data.

With non-censored data, nonparametric *two-sample linear rank statistics* are defined as $\sum_{i=1}^{n_1} \varphi\left(\frac{R_i}{n+1}\right)$, where the nondecreasing function φ defined on $(0, 1)$ is called *the score*, R_i are ranks of the first sample among all observations from both samples, and $n = n_1 + n_2$ is the total sample size (Lehmann 1975). These test statistics are also invariant with respect to any strictly increasing transformations of data because such transformations do not change the ranks. We are going to note that some of these non-censored linear rank statistics are special cases of weighted logrank statistics.

Note. It is difficult to generalize the term *rank* to censored data because censoring makes ordering of failure times unclear. The class W_K provides a generalization of linear rank statistics to censored data through its invariance property but avoids any direct reference to the ranks.

Examples of weighted logrank tests

1. For $W(s) = 1$, we get the *logrank test* (Mantel 1966).

In non-censored data, the logrank test is equivalent to the *Savage exponential scores test* (Savage 1956) with scores

$$\varphi\left(\frac{R_i}{n+1}\right) = \sum_{j=1}^{R_i} \frac{1}{n-j+1}.$$

These scores are expressions for $E X_{(R_i)}$, expected values of order statistics for a random sample of size n from the exponential distribution with parameter 1. Savage test is the most powerful test against changes in scale between two exponentially distributed samples or against shifts in location between two samples with Gumbel distributions.

2. For $W(s) = \frac{\bar{Y}(s)}{n+1}$, we get the *Gehan-Wilcoxon test* (Gehan 1965).

In non-censored data, the Gehan-Wilcoxon test is equivalent to the *Wilcoxon rank-sum test* (Fleming and Harrington 1991, Example 3.3.1) with scores

$$\varphi\left(\frac{R_i}{n+1}\right) = \frac{R_i}{n+1}.$$

Wilcoxon test is the most powerful test against shifts in location between two samples with logistic distributions.

This test puts more weight on early differences in hazard functions than on differences that occur later.

3. For $W(s) = \widehat{S}(s-)$, we get the *Prentice-Wilcoxon test* (Prentice 1978). This is another generalization of the *Wilcoxon rank-sum test* to censored data. It uses the Kaplan-Meier estimator as the weight (left-continuous version is used to assure predictability).

Note. The Prentice test differs from the Gehan test by using the Kaplan-Meier estimator \widehat{S} in place of the empirical distribution of the censored failure time. If the data are uncensored, $\frac{\bar{Y}}{n+1}$ and \widehat{S} are both estimators of the survival function. However, in censored data $\frac{\bar{Y}(s)}{n+1}$ estimates the probability of being at risk, which is affected by the censoring distribution, unlike the Kaplan-Meier estimator, which estimates the survival function. This is why the Prentice-Wilcoxon test is the preferred variant.

4. For $W(s) = \widehat{S}(s-)^\rho [1 - \widehat{S}(s-)]^\gamma$, where $\rho, \gamma \geq 0$ are selected constants, we get the *Fleming-Harrington $G(\rho, \gamma)$ class of test statistics* (Fleming and Harrington 1981; Harrington and Fleming 1982). This class includes increasing, decreasing, and non-monotone weights depending on the choice of ρ and γ . The logrank test is a special case for $\rho = \gamma = 0$, the Prentice-Wilcoxon test is a special case for $\rho = 1, \gamma = 0$.

Moments of weighted logrank statistics

The statistic W_K can be written as

$$W_K = \int_0^\infty \frac{K(s)}{\bar{Y}_1(s)} d\bar{M}_1(s) - \int_0^\infty \frac{K(s)}{\bar{Y}_2(s)} d\bar{M}_2(s) + \int_0^\infty K(s)[d\Lambda_1(s) - d\Lambda_2(s)]. \quad (5.3)$$

The first two terms are martingale integrals; the third term vanishes if the null hypothesis holds. This representation is the key to the proof of the following theorem specifying the finite sample moments of W_K .

Theorem 5.1.

- (i) $E W_K = \int_0^\infty E K(s) d[\Lambda_1(s) - \Lambda_2(s)]$. Under $H_0 : \Lambda_1 = \Lambda_2$, $E W_K = 0$.
(ii) Under $H_0 : \Lambda_1 = \Lambda_2 \equiv \Lambda$,

$$\sigma_K^2 \equiv \text{var } W_K = \int_0^\infty E \left\{ \frac{\bar{Y}(s)}{\bar{Y}_1(s)\bar{Y}_2(s)} K^2(s) \right\} [1 - \Delta\Lambda(s)] d\Lambda(s). \quad \diamond$$

Note. Take W_{K_1} and W_{K_2} two statistics from the class W_K . Then, under H_0 ,

$$\text{cov}(W_{K_1}, W_{K_2}) = \int_0^\infty E \left\{ \frac{\bar{Y}(s)}{\bar{Y}_1(s)\bar{Y}_2(s)} K_1(s)K_2(s) \right\} [1 - \Delta\Lambda(s)] d\Lambda(s).$$

The next theorem introduces an unbiased estimator of σ_K^2 .

Theorem 5.2. *Let the null hypothesis be true. Define*

$$\begin{aligned}\widehat{\sigma}_K^2 &= \int_0^\infty K^2(s) \left(\frac{1}{\overline{Y}_1(s)} + \frac{1}{\overline{Y}_2(s)} \right) \left(1 - \frac{\Delta \overline{N}(s) - 1}{\overline{Y}(s) - 1} \right) d\widehat{\Lambda}(s) \\ &= \int_0^\infty \frac{K^2(s)}{\overline{Y}_1(s)\overline{Y}_2(s)} \left(1 - \frac{\Delta \overline{N}(s) - 1}{\overline{Y}(s) - 1} \right) d\overline{N}(s),\end{aligned}$$

where $\widehat{\Lambda}(t) = \int_0^t d\overline{N}(s)/\overline{Y}(s)$ is the Nelson-Aalen estimator of the common cumulative hazard calculated from both samples. Then $E \widehat{\sigma}_K^2 = \sigma_K^2$. \diamond

It is not difficult to verify that for the logrank test, $\widehat{\sigma}_K^2$ is equal to the variance estimator $\sum V_j$ proposed in the previous section by considering hypergeometric distribution and ignoring non-independence of the terms included in the statistic.

5.4. Asymptotic results for weighted logrank statistics

Take $\tau > 0$ such that $P[Y_{ki}(\tau) = 1] > \delta > 0$ for $k = 1, 2$ and all $i = 1, \dots, n$. Assume that $\Lambda_k(\tau) < \infty$ for $k = 1, 2$. If (T_{ki}, C_{ki}) , $i = 1, \dots, n_k$ are identically distributed within group k then by Lemma 4.1 there exist deterministic functions $\pi_k(t) = P[Y_{ki}(t) = 1]$ such that

$$\sup_{t \in \langle 0, \tau \rangle} \left| \frac{1}{n_k} \overline{Y}_k(t) - \pi_k(t) \right| \xrightarrow{P} 0 \quad \text{and} \quad \pi_k(t) > \delta > 0 \text{ for } t \in \langle 0, \tau \rangle. \quad (5.4)$$

If the data (i.e., censoring times) are not identically distributed, the existence of functions π_1, π_2 satisfying (5.4) is taken as an assumption. Denote $n = n_1 + n_2$ and assume that $n_k/n \rightarrow a_k > 0$ as $n \rightarrow \infty$, $k = 1, 2$. It follows that $n^{-1}\overline{Y}(s)$ converges in probability to the function $\pi(s) = a_1\pi_1(s) + a_2\pi_2(s)$, uniformly in time.

Note. Under the null hypothesis, the distribution of T_{ki} is the same in both groups but the censoring distributions may not be the same, so in general $\pi_1(t) \neq \pi_2(t)$ even when H_0 holds.

We will formulate a result on the weak convergence of the weighted logrank statistic under the null hypothesis. The statistic is viewed as a process developing over time, i.e.,

$$W_K(t) = \int_0^t K(s) d(\widehat{\Lambda}_1 - d\widehat{\Lambda}_2)(s),$$

with

$$K(s) = \sqrt{\frac{n}{n_1 n_2}} W(s) \frac{\overline{Y}_1(s)\overline{Y}_2(s)}{\overline{Y}(s)}.$$

Theorem 5.3. Let $W_K(t)$ be a weighted logrank statistic with the weight $W(s)$ of the form $W(s) = f(\widehat{S}(s-))$, where f is a bounded nonnegative continuous function with bounded variation on $(0, 1)$ and $\widehat{S}(s)$ is the pooled Kaplan-Meier estimator at s . Suppose

$$\sigma^2(t) = \int_0^t (h_1(s) + h_2(s)) (1 - \Delta\Lambda(s)) d\Lambda(s) < \infty$$

for all $t \leq \tau$, where $h_k(s)$ is the limit in probability of $K^2(s)/\bar{Y}_k(s)$. Let

$$\widehat{\sigma}^2(t) = \int_0^t \frac{K^2(s)}{\bar{Y}_1(s)\bar{Y}_2(s)} \left[1 - \frac{\Delta\bar{N}(s) - 1}{\bar{Y}(s) - 1} \right] d\bar{N}(s).$$

Then $W_K(t)$ (taken as a process over time) converges weakly to a time-transformed Brownian motion $W(\sigma^2(t))$ on $D(0, \tau)$ and $\widehat{\sigma}^2(t) \xrightarrow{P} \sigma^2(t)$ as $n \rightarrow \infty$ uniformly over $t \in (0, \tau)$. In particular,

$$\frac{W_K(\tau)}{\sqrt{\widehat{\sigma}^2(\tau)}} \xrightarrow{D} N(0, 1). \quad \diamond$$

Note.

- We present the proof with the additional condition that the distribution of T_{ki} is continuous, however, the theorem also holds for distributions that are not continuous.
- The theorem also holds for $W(s) = f(\widehat{\pi}(s))$, where $\widehat{\pi}(s) = \bar{Y}(s)/n$ (Gehan-Wilcoxon test statistic).
- Asymptotic normality of W_K also holds when the statistic is calculated over the whole range of the data, i.e., when τ is replaced by $\inf\{t : \bar{Y}_1(t) = 0 \text{ or } \bar{Y}_2(t) = 0\}$. However, the conditions must be formulated a little bit more carefully and the proof needs additional work at some places.

The hypothesis $H_0 : S_1(t) = S_2(t)$ is rejected when

$$\frac{|W_K(\tau)|}{\sqrt{\widehat{\sigma}^2(\tau)}} \geq u_{1-\alpha/2} \quad \text{or, equivalently,} \quad \frac{W_K^2(\tau)}{\widehat{\sigma}^2(\tau)} \geq \chi_1^2(1 - \alpha/2).$$

Theorem 5.3 assures that the level of this test converges to α as $n \rightarrow \infty$.

5.5. Behavior of weighted logrank tests under the alternative

Consistency

First, let us investigate consistency of weighted logrank tests.

Definition 5.1. Let W_n be a sequence of test statistics with α -level rejection regions R_n , $n = 1, 2, \dots$. The sequence W_n is consistent against the alternative H_A if

$$\lim_{n \rightarrow \infty} P[W_n \in R_n | H_A] = 1. \quad \nabla$$

Let $S_k(t)$ be the survival function of T in group k and let $\lambda_k(t)$ be the associated hazard function. We will be interested in two special alternatives. The alternative $H_1 : \lambda_1(t) \geq \lambda_2(t)$ (with strict inequality at some t) is called the *ordered hazards alternative*. The alternative $H_2 : S_2(t) \geq S_1(t)$ (with strict inequality at some t) is called the *alternative of stochastic ordering*. Clearly, H_1 implies H_2 .

Let t_0 be a point such that $\Lambda_1(t_0) > \Lambda_2(t_0)$ and $\pi_k(t_0) > 0$ for $k = 1, 2$. Consider weighted logrank statistics with $W(t) = f(\widehat{S}(t-))$ or $W(t) = f(\widehat{\pi}(t))$. We have

$$K(s) = \sqrt{\frac{n_1 n_2}{n}} W(s) \frac{\widehat{\pi}_1(s) \widehat{\pi}_2(s)}{\widehat{\pi}(s)}.$$

Since $\widehat{\pi}_k(s) \xrightarrow{P} \pi_k(s)$ and $W(s) \xrightarrow{P} w(s)$, a left continuous function such that $w(t_0) > 0$, $K(s)$ converges to ∞ on a non-null set. Under the ordered hazards alternative, according to Theorem 5.1(i), the mean of W_K converges to infinity; since its variance estimator is bounded in probability, it follows that W_K is consistent against ordered hazards.

Consistency against stochastic ordering does not hold in general. It can be shown that W_K is consistent against H_2 if

$$\int_0^\infty w(s) \frac{\pi_1(s) \pi_2(s)}{\pi(s)} [d\Lambda_1(s) - d\Lambda_2(s)] > 0.$$

After performing integration by parts, this condition can be expressed as

$$\int_0^\infty [\Lambda_1(s) - \Lambda_2(s)] d \left[w(s) \frac{\pi_1(s) \pi_2(s)}{\pi(s)} \right] < 0.$$

The left-hand side is negative if and only if $w(s) \frac{\pi_1(s) \pi_2(s)}{\pi(s)}$ is a decreasing function of s . Since $\pi_1(s) \pi_2(s) / \pi(s)$ is decreasing, a sufficient condition is that $w(s)$ is non-increasing in s , in other words that the function f that defines the weight is non-decreasing. Then W_K is consistent against stochastic ordering. However, when f decreases consistency need not hold. Thus, $G(\rho, 0)$ statistics, including the logrank and Prentice-Wilcoxon, are always consistent against stochastic ordering. On the other hand, $G(\rho, \gamma)$ statistics with $\gamma > 0$ may not be.

Power

Power of weighted logrank tests is investigated in the local asymptotic sense. For a given $n = n_1 + n_2$, let the survival functions in the two groups be specified as $S_k^{(n)} = S(g(t) + \theta_k^{(n)})$

where S is a known continuous survival function with a differentiable density, $g(t)$ is some differentiable increasing function from $(0, \infty)$ to \mathbb{R} , $\theta_1^{(n)} = \theta_0 + c/\sqrt{n}$, and $\theta_2^{(n)} = \theta_0 - c/\sqrt{n}$, where c is a positive constant.

It can be shown that, under these conditions, the test statistic that maximizes asymptotic power has the weight

$$W(t) = h'(S^{-1}(\widehat{S}(t-))),$$

where $h = \log(-S'/S)$ is the logarithm of hazard for the distribution S and \widehat{S} is the pooled Kaplan-Meier estimator. Tests that maximize power in this sense are called locally asymptotically efficient.

For example, if the data arise from a time-transformed shift in an extreme-value distribution with survival function $S(t) = \exp(-e^t)$, we get $h(t) = \log(e^t) = t$ and $h' = 1$. Hence, the statistic with $W(t) = 1$, i.e., the logrank, is locally efficient against shift alternatives in the extreme value distribution.

Next, take the logistic distribution with $S(t) = 1 - (1 + \exp(-t))^{-1}$. Then $h(t) = -\log(1 + \exp(-t))$, $h'(t) = \exp(-t)(1 + \exp(-t))^{-1} = S(t)$ and $h'(S^{-1}(\widehat{S}(t-))) = S(S^{-1}(\widehat{S}(t-))) = \widehat{S}(t-)$. Hence, the Prentice-Wilcoxon statistic is locally efficient against shift alternatives in logistic distribution.

These results can be extended by taking advantage of the generality of the time transformation g . The logrank can be shown to be efficient not only against shifts in the extreme value distribution, but against any proportional hazards alternatives, that is, alternatives $\lambda_2(t) = \theta\lambda_1(t)$ for $0 < \theta \neq 1$ independent of time and any hazard function λ_1 .

The Gehan-Wilcoxon statistic uses a weight that is not a function of $\widehat{S}(t-)$; therefore it cannot be efficient against any location-shift alternative.

See Section 7.4 of Fleming and Harrington (1991) for more detailed discussion of local asymptotic efficiency of weighted logrank tests.

A. Appendix

A.1. Useful failure time distributions

Unless stated otherwise, the argument t of densities, distribution functions, survival functions and hazard functions always takes values in the interval $\langle 0, \infty \rangle$.

A.1.1. Exponential distribution

$T \sim \text{Exp}(\lambda), \lambda > 0$

Density: $f(t) = \lambda e^{-\lambda t}$

Distribution function: $F(t) = 1 - e^{-\lambda t}$

Survival function: $S(t) = e^{-\lambda t}$

Hazard function: $\lambda(t) = \lambda$

Expectation: $E T = 1/\lambda$

Mean residual lifetime: $r(t) = 1/\lambda$

Exponential distribution is the only continuous distribution that possesses so called *memoryless property*:

$$\forall s > 0, \forall t > 0: \quad \mathbb{P}[T > t + s | T > s] = \mathbb{P}[T > t] = e^{-\lambda t}.$$

Relationship to Gumbel distribution

Take $U \sim \text{Exp}(1)$ and consider the random variable $W = \log U$, which can take on any real value. The distribution function of W is

$$\mathbb{P}[W \leq t] = \mathbb{P}[T \leq e^t] = 1 - e^{-e^t}, \quad t \in \mathbb{R}.$$

The density of W is

$$f_W(t) = e^{t-e^t}, \quad t \in \mathbb{R}.$$

This distribution is called *the extreme value (Gumbel) distribution*.

Take $T \sim \text{Exp}(\lambda)$. Then $\lambda T \sim \text{Exp}(1)$, $\log \lambda T = W$ and $\log T = -\log \lambda + W$, where W is a Gumbel random variable. Consider the loglinear model $\lambda = e^{\beta^\top \mathbf{Z}}$. Then $\log T$ satisfies the linear model

$$\log T = -\beta^\top \mathbf{Z} + W,$$

where W is a random error term distributed according to Gumbel distribution.

A.1.2. Weibull distribution

$$T \sim W(\lambda, \alpha), \lambda > 0, \alpha > 0$$

Density: $f(t) = \alpha \lambda^\alpha t^{\alpha-1} e^{-(\lambda t)^\alpha}$

Survival function: $S(t) = e^{-(\lambda t)^\alpha}$

Hazard function: $\lambda(t) = \alpha \lambda^\alpha t^{\alpha-1}$

Expectation: $E T = \Gamma(1 + \alpha^{-1})/\lambda$

Relationship to exponential distribution

- Let $T \sim W(\lambda, 1)$. Then $T \sim \text{Exp}(\lambda)$.
- Let $U \sim \text{Exp}(1)$. Define $T = \frac{1}{\lambda} U^{1/\alpha}$. Then $T \sim W(\lambda, \alpha)$.
- Let $T \sim W(\lambda, \alpha)$. Then $U = (\lambda T)^\alpha \sim \text{Exp}(1)$.

Relationship to Gumbel distribution

Take $T \sim W(\lambda, \alpha)$. Then $(\lambda T)^\alpha \sim \text{Exp}(1)$, $\log(\lambda T)^\alpha = W$, and $\log T = -\log \lambda + \alpha^{-1}W$, where W is a Gumbel random variable. Thus, $\log T$ satisfies a location-scale model where $-\log \lambda$ represents the location parameter and $1/\alpha$ represents the scale parameter.

Consider the loglinear model $\lambda = e^{\beta^\top \mathbf{Z}}$. Then $\log T$ satisfies the linear model

$$\log T = -\beta^\top \mathbf{Z} + \alpha^{-1}W,$$

where W is a random error term distributed according to Gumbel distribution and α^{-1} controls the variability of the error term.

A.1.3. Gamma distribution

$$T \sim \Gamma(a, p), a > 0, p > 0$$

Density: $f(t) = \frac{a^p}{\Gamma(p)} t^{p-1} e^{-at}$

Expectation: $E T = \frac{p}{a}$

Survival function: $S(t) = 1 - \text{IG}(p, at)$, where $\text{IG}(p, t) = \frac{1}{\Gamma(p)} \int_0^t x^{p-1} e^{-x} dx$ is the incomplete Gamma function.

Hazard function: Does not have a tractable form. When $p > 1$ then $\lambda(0) = 0$, $\lambda(t)$ is increasing, and $\lim_{t \rightarrow \infty} \lambda(t) = a$. When $p < 1$ then $\lambda(0) = \infty$, $\lambda(t)$ is decreasing, and $\lim_{t \rightarrow \infty} \lambda(t) = a$.

Relationship to exponential distribution

- Let $T \sim \Gamma(a, 1)$. Then $T \sim \text{Exp}(a)$.

A.1.4. Raleigh distribution

Density: $f(t) = (\lambda_0 + \lambda_1 t) e^{-(\lambda_0 t + \frac{1}{2} \lambda_1 t^2)}$, $\lambda_0 > 0, \lambda_1 > 0$

Survival function: $S(t) = e^{-(\lambda_0 t + \frac{1}{2} \lambda_1 t^2)}$

Hazard function: $\lambda(t) = \lambda_0 + \lambda_1 t$

A.1.5. Gompertz distribution

Density: $f(t) = \lambda_1 \exp\left\{-\frac{\lambda_1}{\lambda_2} (e^{\lambda_2 t} - 1) + \lambda_2 t\right\}$, $\lambda_1 > 0, \lambda_2 > 0$

Survival function: $S(t) = \exp\left\{-\frac{\lambda_1}{\lambda_2} (e^{\lambda_2 t} - 1)\right\}$

Hazard function: $\lambda(t) = \lambda_1 e^{\lambda_2 t}$

A.1.6. Log-logistic distribution

Density: $f(t) = \kappa \varrho \frac{(\varrho t)^{\kappa-1}}{[1 + (\varrho t)^\kappa]^2}$, $\varrho > 0, \kappa > 0$

Survival function: $S(t) = \frac{1}{1 + (\varrho t)^\kappa}$

Hazard function: $\lambda(t) = \kappa \varrho^\kappa \frac{t^{\kappa-1}}{1 + (\varrho t)^\kappa}$

A.1.7. Geometric distribution

$T \sim \text{Geo}(p), p \in (0, 1)$

This is a discrete distribution with values $0, 1, 2, \dots$

Density:	$P[T = t] = p(1 - p)^t, \quad t = 0, 1, 2, \dots$
Expectation:	$E T = \frac{1 - p}{p}$
Survival function:	$S(t) = (1 - p)^{[t]+1}, \quad t > 0$, where $[t] = \max\{j \in \mathbb{Z} : j \leq t\}$ is the lower whole part of the real argument t
Hazard function:	$\lambda(t) = p, \quad t = 0, 1, 2, \dots$

Relationship to exponential distribution

- Let $U \sim \text{Exp}(\lambda)$. Then $T = [U] \sim \text{Geo}(p)$, where $p = 1 - e^{-\lambda}$.

Geometric distribution is the only discrete distribution that possesses the *memoryless property*:

$$\forall s > 0, \forall t > 0 : \quad P[T > t + s | T > s] = P[T > t] = (1 - p)^{[t]+1}.$$

A.2. Results from mathematical analysis and martingale theory

A.2.1. Integration by parts for Lebesgue-Stieltjes integral

Theorem A.1. (Fleming & Harrington, Theorem A.1.2) Let $F : \langle 0, \infty \rangle \rightarrow \mathbb{R}$ and $G : \langle 0, \infty \rangle \rightarrow \mathbb{R}$ be right-continuous functions of bounded variation on any finite interval. Let $\Delta F(x) = F(x) - F(x-)$, $\Delta G(x) = G(x) - G(x-)$. Then

$$\begin{aligned} F(t)G(t) - F(0)G(0) &= \int_0^t F(x-)dG(x) + \int_0^t G(x) dF(x) \\ &= \int_0^t F(x-)dG(x) + \int_0^t G(x-) dF(x) + \sum_{0 < x \leq t} \Delta F(x)\Delta G(x). \quad \diamond \end{aligned}$$

Note.

$$\int_0^t F(x)dG(x) = \int_0^t F(x-)dG(x) + \sum_{0 < x \leq t} \Delta F(x)\Delta G(x).$$

A.2.2. Random processes and martingales

Consider a probability space (Ω, \mathcal{F}, P) .

Definition A.1. A family $\{\mathcal{F}_t : t \geq 0\}$ of sub- σ -algebras of a σ -algebra \mathcal{F} is called a *filtration* if, for all $s \leq t$, $\mathcal{F}_s \subset \mathcal{F}_t$. ▽

Definition A.2. Let $\{\mathcal{F}_t : t \geq 0\}$ be a filtration. A random process $X(t)$, $t \geq 0$, is called *adapted to the filtration* \mathcal{F}_t if $X(t)$ is \mathcal{F}_t -measurable for any $t \geq 0$. ▽

Notation.

- $X(t-) = \lim_{h \searrow 0} X(t-h)$
- $\mathcal{F}_{t-} = \sigma\left\{\bigcup_{h>0} \mathcal{F}_{t-h}\right\}$

Definition A.3. Let $X(t)$, $t \geq 0$, be a right-continuous process with left-hand limits and let $\{\mathcal{F}_t : t \geq 0\}$ be a filtration. Let $X(t)$ be adapted to \mathcal{F}_t and $E|X(t)| < \infty$ for all $t < \infty$.

- (i) X is called a *martingale with respect to the filtration* \mathcal{F}_t if $E[X(t+s) | \mathcal{F}_t] = X(t)$ almost surely for all $s \geq 0$, $t \geq 0$.
- (ii) X is called a *submartingale with respect to the filtration* \mathcal{F}_t if $E[X(t+s) | \mathcal{F}_t] \geq X(t)$ almost surely for all $s \geq 0$, $t \geq 0$. ▽

Note.

- Let $X(t)$ be an \mathcal{F}_t -martingale with $X(0) = 0$ a.s. Then $E X(t) = 0$ for all $t \geq 0$.
- Let $X(t)$ be an \mathcal{F}_t -martingale. Then $E[X(t) | \mathcal{F}_{t-}] = X(t-)$ a.s.

Definition A.4. A process $X(t)$ is called *predictable with respect to the filtration* \mathcal{F}_t if it is measurable with respect to the smallest σ -algebra on $\mathbb{R}_0^+ \times \Omega$ generated by left continuous \mathcal{F}_t -measurable processes. ▽

Note. An equivalent definition of predictability is this: $X(t, \omega)$ is \mathcal{F}_t -predictable if and only if it is a mapping $(0, \infty) \times \Omega \rightarrow \mathbb{R}$, which is measurable with respect to the *predictable σ -algebra*

$$\sigma\{\{0\} \times A : A \in \mathcal{F}_0, (t, s) \times A : t < s \in \mathbb{R}_0^+, A \in \mathcal{F}_t\}.$$

Note. A left continuous \mathcal{F}_t -measurable process $A(t)$ is predictable with respect to \mathcal{F}_t .

Definition A.5. An \mathcal{F}_t -measurable process $\{N(t) : t \geq 0\}$ is a *counting process* if $N(0) = 0$, $N(t) < \infty$ a.s., and almost all its paths are right-continuous and piecewise constant with jumps of size 1. ▽

Note. A counting process is a submartingale.

A.3. Brownian motion

A.3.1. Standard Brownian motion

The Brownian motion (also called the Wiener process) is a random process $W(t)$, $t \in (0, \infty)$, that satisfies the following requirements:

- (i) $W(0) = 0$ almost surely;
- (ii) almost all paths of $W(t)$ are continuous;
- (iii) for any $n > 1$ and $0 \leq t_1 < t_2 < \dots < t_n$, $W(t_1)$, $W(t_2) - W(t_1), \dots, W(t_n) - W(t_{n-1})$ are independent; (independent increments);
- (iv) for any $0 \leq t < s$, $W(s) - W(t) \sim N(0, s - t)$.

The Brownian motion has a number of additional interesting properties:

- At all $t \geq 0$, $E W(t) = 0$, $\text{var } W(t) = t$.
- At all $s, t \geq 0$, $\text{cov}(W(t), W(s)) = s \wedge t$.
- If $W(t)$ is a Brownian motion then $\sigma^{-1/2}W(\sigma t)$ is also a Brownian motion.
- $W(t)$ is a martingale with respect to its history; its predictable variation process is $\langle W, W \rangle(t) = t$.
- The sample paths of $W(t)$ are not differentiable at any t a.s.
- The sample paths of $W(t)$ do not have bounded variation on any interval.

A.3.2. Time-transformed Brownian motion

The process $V = \int f dW$ is called *time-transformed Brownian motion*. It has all the properties of a Brownian motion except variance function. Its variance function is $\text{var } V(t) \equiv h(t) = \int_0^t f^2(s) ds$. When $f(s) \equiv 1$, the time-transformed Brownian motion is a standard Brownian motion.

The variance function $h(t)$ can be viewed as a non-decreasing time transformation. We can obtain the time-transformed Brownian motion as $V(t) = W(h(t))$, where W is a standard Brownian motion.

A.3.3. Brownian bridge

Brownian bridge $B(t)$ is a stochastic process defined on the interval $\langle 0, 1 \rangle$, with values $B(0) = B(1) = 0$. It can be obtained from the standard Brownian motion by the transformation

$$B(t) = W(t) - tW(1), \quad t \in \langle 0, 1 \rangle.$$

Brownian bridge is a Gaussian process with zero mean and variance function $\text{var } B(t) = t(1 - t)$. The covariance function for $s < t$ is $\text{cov}(B(s), B(t)) = s(1 - t)$.

A.4. Weak convergence of stochastic processes

In this part we review main features of weak convergence of stochastic processes, in particular convergence of processes with right-continuous sample paths with left-hand limits defined on the interval $\langle 0, \tau \rangle$. The space of such functions is denoted $D\langle 0, \tau \rangle$.

Take a metric space \mathcal{X} and the smallest σ -algebra \mathcal{B} that includes all the open sets contained in \mathcal{X} . A stochastic process with sample paths belonging to \mathcal{X} is a measurable mapping $(\Omega, \mathcal{A}) \rightarrow (\mathcal{X}, \mathcal{B})$.

The metric that defines open sets on $D\langle 0, \tau \rangle$ is called Skorokhod metric. Let Φ be the set of all strictly increasing continuous functions f mapping $\langle 0, \tau \rangle$ onto $\langle 0, \tau \rangle$, so that $f(0) = 0$ and $f(\tau) = \tau$.

Definition A.6. For any $g, h \in D\langle 0, \tau \rangle$ define

$$d(g, h) = \inf \left\{ \varepsilon > 0 : \exists f \in \Phi \text{ s.t. } \sup_{t \in \langle 0, \tau \rangle} |f(t) - t| \leq \varepsilon \text{ and } \sup_{t \in \langle 0, \tau \rangle} |g(t) - h(f(t))| \leq \varepsilon \right\}.$$

The distance d is called *Skorokhod distance*. ▽

This is almost the supremal distance except that the two functions are evaluated at slightly different arguments. Skorokhod distance defines a topology of open sets on $D\langle 0, \tau \rangle$; let \mathcal{B}^* be the smallest σ -algebra containing all such open sets. The Skorokhod topology can be metrized by another metric, which makes the space $(D\langle 0, \tau \rangle, \mathcal{B}^*)$ complete and separable. A stochastic process with sample paths contained in $D\langle 0, \tau \rangle$ is a measurable mapping $(\Omega, \mathcal{A}) \rightarrow (D\langle 0, \tau \rangle, \mathcal{B}^*)$.

Definition A.7. Let P_n and P be probability measures on $(\mathcal{X}, \mathcal{B})$. We say that P_n *converges weakly* to P as $n \rightarrow \infty$, (denoted $P_n \Longrightarrow P$), if and only if $P_n(A) \rightarrow P(A)$ for any $A \in \mathcal{B}$ such that $P(\partial A) = 0$, where ∂A is the boundary of the set A . ▽

If the sample space \mathcal{X} is \mathbb{R}^d , weak convergence coincides with convergence in distribution of a random vector X_n to a multivariate distribution P .

Theorem A.2 (Continuous mapping theorem). Let h be a continuous mapping from a metric space $(\mathcal{X}, \mathcal{B})$ to another metric space $(\mathcal{X}', \mathcal{B}')$, let $P_n \Longrightarrow P$ on $(\mathcal{X}, \mathcal{B})$. Then

$$P_n h^{-1} \Longrightarrow P h^{-1}$$

on $(\mathcal{X}', \mathcal{B}')$. ◇

Let X_1, X_2, \dots be a sequence of stochastic processes on $(D\langle 0, \tau \rangle, \mathcal{B}^*)$, let X be a stochastic process on $(D\langle 0, \tau \rangle, \mathcal{B}^*)$ such that $X_n \Longrightarrow X$. Take any $k \geq 1$ and select time points $t_1, \dots, t_k \in \langle 0, \tau \rangle$. The mapping that assigns to any function $f \in D\langle 0, \tau \rangle$ the k -vector of values $(f(t_1), \dots, f(t_k))$ is continuous with respect to the Skorokhod metric. It follows from the continuous mapping theorem that the random vector $(X_n(t_1), \dots, X_n(t_k))^T$ converges in distribution to $(X(t_1), \dots, X(t_k))^T$. This is called the convergence of finite-dimensional distributions. It is a necessary but not sufficient condition for weak convergence of stochastic processes.

A. Appendix

Note. It can be shown that, for $X \in D\langle 0, \tau \rangle$, the mapping $X \rightarrow \sup_{t \in \langle 0, \tau \rangle} |X(t)|$ is continuous with respect to the Skorokhod metric. It follows from the continuous mapping theorem that if $X_n \Rightarrow X$ then

$$\sup_{t \in \langle 0, \tau \rangle} |X_n(t)| \xrightarrow{D} \sup_{t \in \langle 0, \tau \rangle} |X(t)|.$$

Definition A.8. A collection P_n of probability measures on a metric space $(\mathcal{X}, \mathcal{B})$ is called *tight* if for any $\varepsilon > 0$ there exists a compact set $K \subset \mathcal{X}$ such that $P_n(K) > 1 - \varepsilon$ for all n . ∇

Theorem A.3. Let $(\mathcal{X}, \mathcal{B})$ be a complete and separable metric space. Let P_n and P be probability measures on $(\mathcal{X}, \mathcal{B})$. Then

$$P_n \Rightarrow P$$

if and only if both of the following conditions hold:

1. All finite-dimensional distributions of P_n converge to the respective finite-dimensional distributions of P .
2. The collection P_n is tight. \diamond

For stochastic processes in $D\langle 0, \tau \rangle$, there is a sufficient condition for tightness, which goes as follows.

Theorem A.4. The sequence of stochastic processes X_n with sample paths in $D\langle 0, \tau \rangle$ satisfies the tightness condition if for any $\varepsilon > 0$

$$\lim_{\delta \rightarrow 0} \limsup_{n \rightarrow \infty} \mathbb{P} \left[\sup_{|s-t| < \delta} |X_n(s) - X_n(t)| > \varepsilon \right] = 0. \quad \diamond$$
